FOREWORD

The year 1949 marks the close of a dynamic half century. This period has been one of amazing development in the minerals and metals industry—during the last 50 years the United States has achieved preeminence among the nations of the world in producing, processing, and fabricating mineral raw materials.

This volume of MINERALS YEARBOOK for 1949 appears at an opportune time. Today we have reached a position where we must reappraise and reevaluate our ability to produce for the future. In the current unsettled state of the world, the problems before our minerals industry are complex, and their solution appears at this time to be uncertain. There is no doubt that the requirements of the immediate future will necessitate expanded production and increased exploration for new sources of mineral raw materials within the continental limits of the United States and its territorial possessions as well as within the confines of free nations overseas.

It is to be hoped that the 1949 MINERALS YEARBOOK will be studied carefully not only by those directly concerned with the problems of the mineral industry but also by members of the general public who are thinking ahead. Whether or not the United States has reached the apex of its production potential will depend upon good understanding of our mineral position by the American people as well as the initiative, abilities, and enterprise of industry and government. Those who consult this volume cannot fail to appreciate the complexities of an industrial economy and the productive capacity of the American mining industry that is so necessary for the welfare and security of the United States and a free world.

Again I wish to extend to the minerals industries the thanks of the Bureau of Mines staff for their continued cooperation in furnishing data for this volume. This valuable assistance has made it possible to present to the public an authoritative analysis of our Nation's mineral position.

JAMES BOYD, *Director*.

INTRODUCTION

This edition of MINERALS YEARBOOK was improved by revising the basis of the national mineral-production tables so that for 1947–49 they are on the same basis as the State tables (Statistical Summary chapter). Innovations include statistical tables showing the minerals produced in each country (Mineral Production of the World chapter), world production of lead and zinc on a mine basis, total mineral imports and exports of the United States (Review of Mineral Industries chapter), and the mineral production of United States Territories and possessions. The table of contents at the beginning of each chapter was omitted in recognition of the excellence of the index. The manuscript was completed 2 months earlier in the year than was the preceding edition.

A comprehensive check of the accuracy and consistency of the statistics in this volume was performed by John Hozik, assistant editor, aided by K. Joyce D'Amico and Vane N. L. Glendening. The manuscript was edited for style improvement, punctuation, and type specification by Mabel E. Winslow, assisted by Estelle R. Templeton and Anna B. Brown, of the Office of Minerals Reports. Most of the charts were drafted by Adelaide B. Palmer, of the MINERALS YEARBOOK section, and others were prepared under the supervision of Louis F. Perry, Region VIII, Pittsburgh, Pa.

Valued advice on the printing of MINERALS YEARBOOK continued to be given by John H. Ady, Chief of Publications of the United States Department of the Interior and liaison officer between the Department and the United States Government Printing Office.

The principal source of the information contained in this volume is questionnaires completed by many persons in the mineral industries. The significant supplementary data on foreign trade are from the United States Department of Commerce and on foreign production from the United States Department of State. Other information of value is quoted from business magazines, trade associations, scientific journals, and various Government agencies. The following officials cooperated with the Bureau of Mines in compiling production data for their respective States:

Alabama: Walter B. Jones, State geologist, University.
Alaska: B. D. Stewart, commissioner of mines, Department of Mines, Juneau.
California: Olaf P. Jenkins, chief, and Charles V. Averill, supervising mining engineer, California Division of Mines, San Francisco 11.
Florida: Herman Gunter, director, Florida Geological Survey, Tallahassee.
Georgia: Garland Peyton, director, Department of Mines, Mining and Geology, Atlanta.
Illinois: M. M. Leighton, chief, and Walter H. Voskuil, mineral economist, State Geological Survey Division, Urbana.
Iowa: H. Garland Hershey, State geologist, Iowa City.
Kansas: Raymond C. Moore, research director and State geologist, and John C. Frye, executive director, State Geological Survey of Kansas, Lawrence.

Kentucky: Daniel J. Jones, State geologist, Kentucky Geological Survey, Lexington.
Maryland: Joseph T. Singewald, Jr., director, Department of Geology, Mines, and Water Resources, Baltimore 18.
Michigan: Gerald Eddy, State geologist, Lansing.
Missouri: Edward L. Clark, State geologist, Rolla.
New Hampshire: T. R. Meyers, geologist, State Planning and Development Commission, Durham.
New Jersey: Meredith E. Johnson, State geologist, Trenton.
New York: John G. Broughton, State geologist, Albany.
North Carolina: Jasper L. Stuckey, State geologist, Raleigh.
Oklahoma: Robert H. Dott, director, Oklahoma Geological Survey, Norman.
South Dakota: E. P. Rothrock, State geologist, Vermillion.
Texas: John T. Lonsdale, director, Bureau of Economic Geology, University of Texas, Austin 12.
Utah: Arthur L. Crawford, director, Utah Geological and Mineralogical Survey, Salt Lake City.
Virginia: William M. McGill, State geologist, and Linwood H. Warwick, office administrator, Virginia Geological Survey, Charlottesville.
Washington: Sheldon L. Glover, supervisor, Division of Mines and Geology, Olympia.
West Virginia: Paul H. Price, State geologist, Morgantown.
Wisconsin: E. F. Bean, State geologist, Madison 6.

Bureau of Mines statisticians and researchers who rendered substantial assistance to the authors of this volume include the following: In Washington, D. C.—Hope Anderson, Dorothy M. Burch, Emma A. Eastep, Leon W. Geyer, Roberta W. Grunberg, Marjorie Kahn, Naomi W. Kearney, James G. Kirby, Lena M. Lunsford, Ann C. Mahoney, Annie L. Marks, Edith D. McKinney, Zena M. Mohme, Betty M. Moore, Robert C. Morris, Elizabeth R. Parker, and Virginia E. Wrenn. In Juneau, Alaska—Opal Y. Sharman. In Los Angeles, Calif.—Edward T. Knudsen, Adele B. Esser, and Harry L. Scarborough. In San Francisco, Calif.—Leona C. Froehlich and Bettye Lanning. In Denver, Colo.—Helen G. Post and Florence H. Scott. In Salt Lake City, Utah—Alice K. Feltch, Virginia C. Halverson, and LaRu T. Shepherd.

FEBRUARY 1951.

CONTENTS

PART I. GENERAL REVIEWS

Review of the Mineral Industries in 1949

By Allan F. Matthews

PRODUCTION

Value of Production.—Mineral products mined and processed in the United States in 1949 were valued at 10.6 billion dollars, the second-largest output to date. This was 14 percent below the all-time high in 1948. Of the three major groups, fuels and metals declined 17 and 10 percent, respectively, whereas nonmetallic minerals (other than fuels) was virtually unchanged. The fuels in 1949 constituted 75 percent of the total, nonmetallic minerals 15 percent, and metals 10 percent.

The 14-percent decline in value of mineral output in 1949 compared with 1948 was sharper than the decreases in agricultural products (8 percent), all products combined (1 percent), and national income (3 percent). This divergence apparently was a compensation of the spurt by minerals in reaching its 1948 peak, for the output of minerals, all products combined, and national income in 1949 were almost uniformly 10 percent above 1947, although farm products were 6 percent below. The bases of these comparisons are Bureau of Agricultural Economics reports on cash receipts from farm marketings (28,127 million dollars in 1949 and 30,544 million dollars in 1948, excluding Government payments) and Bureau of Foreign and Domestic Commerce reports on gross national product (255.6 billion dollars in 1949 and 259.1 billion dollars in 1948) and national income (216.8 billion dollars in 1949 and 223.5 billion dollars in 1948).

The basis of calculating the total value of mineral production of the United States has been revised to agree with the State totals. The new series is shown in table 1 in the "as reported" columns. The revisions, described in detail in the Statistical Summary of Mineral Production chapter of this volume, are primarily the result of discarding component series measuring the value of mineral products at an advanced stage of processing and substituting series whose points of measurement are at the mine or concentrating mill. This substitution was carried as far as it was possible to go with existing

commodity canvasses. The remaining deficiencies are statistical series for mine values of the limestone, cement rock, and clay used in making cement; limestone for lime; dressed dimension stone (in part); natural-gas liquids; and the nonferrous metals—copper, zinc, lead, gold, silver, antimony, mercury, and tin. If estimates for these replace the cement, lime, dressed stone, natural-gasoline plant liquids, and smelted metals series in the "as reported" columns of table 1, the result is shown in the "adjusted" columns of that table. In other words, the "adjusted" columns are strictly on a mine basis. Data prior to 1947, on either of these new bases, have not yet been derived.

TABLE 1.—Mineral production of the United States, by major groups, 1947–49, in millions of dollars

Mineral group	As reported			Adjusted [1]		
	1947 [2]	1948 [2]	1949	1947	1948	1949
Fuels	7,181	9,495	7,886	7,161	9,472	7,861
Nonmetallics (except fuels)	1,345	1,559	1,567	965	1,085	1,077
Metals	1,084	1,219	1,101	906	1,026	932
Total	9,610	12,273	10,554	9,032	11,583	9,870

[1] Preliminary figures. [2] Revised figures.

Volume of Production.—The physical volume of production in 1949, compared with 1948, decreased 13 percent for minerals, 10 percent for durable manufactures, and 5 percent for nondurable manufactures, according to the Federal Reserve Board. During 1949 the Board's index of mineral production (1935–39=100) dropped from 149 in January to 112 in October and recovered to 141 in November. The annual average was 135 in 1949, compared with the records of 155 in 1948 and 162 in May 1948.

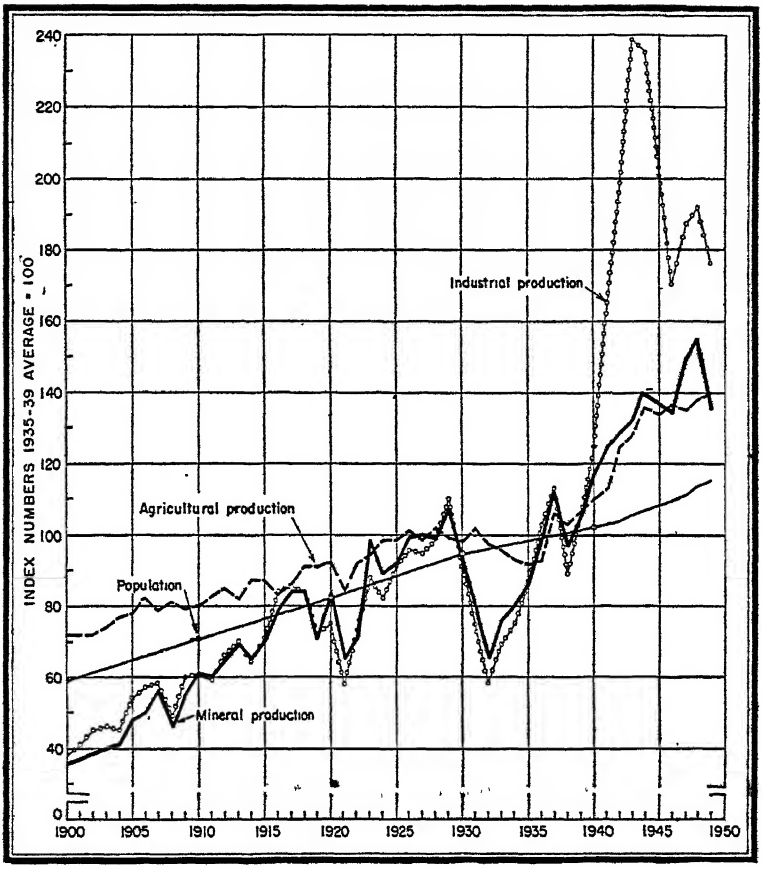

FIGURE 1.—Physical volume of mineral production compared with industrial production (manufactures and minerals), agricultural production, and population, 1900–49. Sources: Federal Reserve Board, U. S. Department of Agriculture, and Bureau of the Census.

The 15-percent decline in tonnage of mineral fuels, as a group, produced in 1949, compared with 1948, was the result of drops of 27 and 9 percent in coal and petroleum, respectively, moderated by gains of 7 and 5 percent in natural gas and natural gasoline, respectively. Nonmetallic minerals other than fuels declined more moderately (2 percent) than either other major group. Record outputs of cement, perlite, pumice, vermiculite, and asbestos were established. The sharpest nonmetallic drops (20 percent or more) involved fluorspar, feldspar, magnesium compounds, and abrasive stone. The metals group decreased 9 percent quantitatively in 1949 output. Ores of iron, molybdenum, and manganese were mined in tonnages 16, 22, and 4 percent, respectively, less than in 1948, a reflection of the 12-percent drop in steel output resulting from an economic recession and from coal and steel work stoppages. Bauxite production slumped 21 percent and copper and zinc 10 and 6 percent, respectively. Zinc output in the Tri-State district was the lowest since 1896. In contrast, lead mining increased 5 percent to the highest level since 1944. An estimate [1] of the zinc-lead ore remaining in the Tri-State district was published by the Bureau of Mines. A new book [2] on the resources of the Southern States includes numerous mineral maps of the region.

Number and Size of Firms.—The average number of mining firms operating in the United States was 33,100 (preliminary figure) in 1949, compared with 35,000 in 1948, 33,800 in 1947, and 36,000 in 1939, according to the Department of Commerce.[3] The 8-percent decrease in number of mining firms in 1939–49 was the only decline among the eight major industrial divisions, and it occurred while the number of industrial firms as a whole advanced 18 percent. Details on the number of new and discontinued businesses in mining and other industries, by size of firm and by States, in 1944–48 were published by the Office of Business Economics.[4] In the United States, 0.2 percent of the mining firms hire 37 percent of the industry's employees, and 3.5 percent of such firms hire 70 percent of the employees, as shown in table 2. This distribution represents a concentration of large companies (size measured by employment) no greater than for all industries as a whole. On the other hand, smelters, refineries, and metalworking plants are considerably more integrated than other manufacturing plants.

TABLE 2.—Percent distribution of firms and of employment in the mining and metal industries in the United States, March 31, 1948, by size of firm

[U. S. Department of Commerce]

Number of paid employees per firm	Number of firms: Mining	Number of firms: Manufacturing: Metals and products	Number of firms: Manufacturing: Other	Number of firms: All industries	Number of paid employees: Mining	Number of paid employees: Manufacturing: Metals and products	Number of paid employees: Manufacturing: Other	Number of paid employees: All industries
0-3	52.7	34.3	46.7	74.4	1.9	0.4	1.1	6.0
4-19	32.6	35.0	32.7	20.6	10.7	2.9	8.5	17.1
20-99	11.2	20.7	15.7	4.1	17.7	8.0	19.1	17.2
100-499	2.8	7.4	4.0	.7	23.2	14.2	23.8	15.7
500-999	.4	1.2	.5	.1	9.9	7.6	9.4	6.3
1,000 or more	.3	1.4	.4	.1	36.6	66.9	38.1	37.7
Total	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0

National Income.—The national income of the United States in 1949 was 217 billion dollars, of which 2 percent originated at mines and 7 percent at metal, oil, coke, stone, and ceramics-manufacturing plants, according to the Department of Commerce. In comparison, 8 percent of the national income was from farms and 0.08 percent from fisheries and forests combined. Of the 4.4-billion-dollar mine income, 42 percent was from coal mining, 36 percent from oil and gas extraction, 12 percent from metal mining, and 10 percent from nonmetallic-mineral mining.

The mining industry's income in 1949 comprised five items, as follows, in millions of dollars: Wages and salaries, 2,938; supplements to wages and salaries (employer contributions for social insurance and private pension funds, pay of military reserve, etc.), 186; income of enterprises before taxes, 1,216; inventory adjustment, 86; net interest, 15; total, 4,441.

TABLE 3.—National income originating in mining and related manufacturing industries in the United States, 1943–49, in millions of dollars

[U. S. Department of Commerce]

Industry	1943	1944	1945	1946 [1]	1947 [1]	1948 [1]	1949
Bituminous coal and lignite	1,130	1,271	1,204	1,241	1,827	2,136	1,582
Anthracite	211	238	219	286	302	349	265
Petroleum and natural gas	671	800	795	925	1,293	1,769	1,612
Metals	507	417	349	324	557	612	539
Nonmetallic minerals	238	224	222	295	371	420	443
Total mining	2,757	2,950	2,789	3,071	4,350	5,277	4,441
Iron and steel products [2]	9,099	9,081	7,376	5,588	7,647	8,720	7,789
Nonferrous metal products	1,939	1,942	1,659	1,748	1,934	2,120	1,974
Products of petroleum and coal	1,502	1,360	1,326	1,679	2,488	3,799	3,044
Stone, clay, and glass products	1,193	1,137	1,147	1,561	1,851	2,120	2,055

[1] Revised figures. [2] Including ordnance.

Equipment and Materials.—The mining industry of the United States spent $740,000,000 on new plants and equipment in 1949, compared with $800,000,000 in 1948, according to the United States Department of Commerce. These amounts constituted 4 percent of the total nonagricultural business expenditures on new plants and equipment.

Mechanization of coal mines continued to progress. Of the bituminous coal and lignite mined underground in 1949, 91.4 percent was cut by machine and 67 percent was loaded by machine—both all-time highs. Underground soft-coal mines purchased 286 mobile loaders, 8 scrapers, 394 loading conveyors, 116 "mother" haulage conveyors, and 543 shuttle cars in 1949. These shipments of mechanical loading equipment, in terms of capacity, were smaller than in any year since 1935.

Industrial explosives sold for consumption in the United States in 1949 totaled 631,230,005 pounds, 13 percent below the 1948 peak of 725,227,173 pounds but nevertheless the third highest recorded. Of the 1949 total, 91,629,597 pounds were permissible high explosives, 505,601,047 were other high explosives, 20,076,925 were black blasting powder, and 13,922,436 were liquid-oxygen explosives. Coal mining used 39 percent of these explosives, construction (railway and other) 21 percent, nonmetal mining (including quarrying) 19 percent, metal mining 18 percent, and other activities 3 percent. Estimated quantities of ingredients contained in explosives consumed in the United States in 1949 were as follows, in million pounds: Sodium nitrate 222, explosive oil (nitroglycerin, etc.) 156, ammonium nitrate 117, sulfur 13, nitrotoluenes and nitrocellulose 5, antacid 5, charcoal 3, carbonaceous combustible material 60, and wrapper paper and paraffin 37. The nitrogen content of these ingredients was 107 million pounds.[5]

Industrial consumption of electric power in the United States was estimated by the Federal Power Commission as 157 billion kilowatt-hours in 1947 compared with 134 billion in 1946. The distribution in 1946 comprised 12 billion kilowatt-hours for mining (5.6 coal, 3.5 metal, 1.6 nonmetallic mineral, and 1.0 petroleum and gas); 19 for iron and steel products; 12 for nonferrous metal products; 7 for stone, clay, and glass products; 6 for products of petroleum and coal, 22 for chemicals and allied products, and 56 billion kilowatt-hours for other manufactures. Unfortunately this statistical series was discontinued after the 1946 data were compiled.

---

[5] Grumberg, Roberta W., Consumption of Industrial Explosives Decreases in 1949: Bureau of Mines Mineral Industry Surveys, Mineral Market Report 1908, 1950, 10 pp. (processed).

Productivity.—The 1949 rate of output of bituminous coal and lignite was a record-breaking 6.4 net tons per man-day, and that of anthracite was 2.9 tons, exceeded only in 1939–42. Other Bureau of Mines data indicate that 1.4 gross tons of usable iron and manganiferous ores were mined per man-hour in 1949 (preliminary figure), compared with 1.5 in 1948 and 1.4 in 1947. The decrease in 1949 was attributed partly to a 4-percent increase in the proportion of iron ore mined underground.

Over the past third of a century the domestic mining industry made substantial gains in productivity. The index of output per man-hour (1939=100), prepared by the Bureau of Labor Statistics and the Works Progress Administration, rose from 49 in 1915 to a record 111 in 1947 and then subsided slightly to 108 in 1949.[6] The upward trend was determined principally by greater mechanization and by more open-pit mining compared with underground operations. These technologic gains overcame, by a wide margin, the disadvantageous factor of decreasing grade of ores extracted.

TABLE 4.—Output per man-hour in the mining industry, 1935, 1943, and 1947–49

[Bureau of Labor Statistics indexes: 1939=100]

Year	Output per man-hour						Production	Man-hours
	Bituminous coal	Anthracite	Iron [1]	Copper [2]	Lead and zinc [2]	Total mining [3]	Total mining	
1935	82.4	79.3	87.7	97.5	99.5	84.9	88.0	103.7
1943	98.7	87.5	96.9	103.6	75.3	101.5	139.6	137.5
1947	112.1	90.5	106.0	110.8	76.5	111.1	147.7	133.0
1948	111.7	90.5	105.5	106.2	82.3	110.9	147.4	132.9
1949	109.2	90.6	101.6	105.9	85.1	108.3	119.0	109.9

[1] Based on usable ore (direct smelting ore plus beneficiated ore), not on crude ore.
[2] Based on recoverable metal, not on ore mined.
[3] Comprises the five industries shown plus the petroleum and natural gas industry. The series for the latter industry was "not considered sufficiently reliable for publication separately, although satisfactory for inclusion in the combined indexes."

[6] Searle, Allan D., and Taylor, Harriet S., Trends in Output per Man-Hour in Mining, 1935–49: Bureau of Labor Statistics, July 1950, 40 pp. (mimeographed).

TRANSPORTATION

Railroads.—Minerals comprise over half of the freight hauled by rail in the United States. The revenue freight originated by class 1 railroads in 1949 totaled 1,227 million short tons, of which 303 were bituminous coal, 37 anthracite, 19 coke, and 295 were other products of mines (including crude petroleum). The corresponding 1948 figures were 430, 48, 23, and 345 million tons, respectively, according to the Interstate Commerce Commission.

Pipelines.—Interstate and export movements of natural gas (including gas stored or lost in transmission) made a record gain of 25 percent in 1948 to 1,757 billion cubic feet, one-third of the marketed production. Petroleum refineries received by pipeline 1,434 million barrels of crude in 1949, compared with 1,475 in 1948. Pipelines for petroleum and refined products in the United States had a mileage of 152,814 in 1949, in contrast to 127,351 in 1941 and 90,170 in 1926. A report [7] showed the distribution by State and by size of these pipelines.

TABLE 5.—Shipments of various mineral products in the United States, by method of transportation in 1949, in thousands of short tons

Mineral product	Railroad	Boat	Truck	Pipeline	Not specified	Total
Cement	30,167	590	7,986			38,743
Coal:						
Bituminous and lignite	356,602	21,828	47,787			426,217
Pennsylvania anthracite	35,232		6,088			41,320
Coke (including breeze)	24,295	1,015	1,586			26,896
Fluorspar	184	53				237
Fuel briquets and packaged fuel	1,951		551			2,502
Iron and manganiferous ores	20,200	75,600				95,800
Natural gas				154,900		154,900
Petroleum [1]	[2] 5,000	49,000	(2)	217,000		271,000
Sand and gravel	70,035	19,253	219,624		10,192	319,104
Slag—iron blast furnace	9,961	402	10,922			21,285
Stone, crushed	71,640	21,419	120,454		8,895	222,408

[1] Domestic only. Data in corresponding table of Minerals Yearbook, 1948, included imported petroleum.
[2] Transportation by truck included with railroad.

[7] Coumbe, A. T., and Avery, I. F., Crude-Oil and Refined Products Pipe-Line Mileage in the United tates, Jan. 1, 1950: Bureau of Mines Inf. Circ. 7585, 1950, 8 pp. (processed).

CONSUMPTION AND SELF-SUFFICIENCY

Demand for natural gas, natural gasoline, cement, and phosphate rock—alone among the most significant minerals—was strong enough in 1949 to register record consumption. Use of bituminous coal and anthracite declined 14 and 25 percent, respectively, in 1949 compared with 1948, owing to a mid-year reduction in the level of industrial operations, competition from other fuels, abnormally warm weather, and work stoppages. Even the demand for crude petroleum dropped off 6 percent, largely because of warm weather and displacement by natural gas. The gains for natural gas and natural gasoline were 6 and 7 percent, respectively. Iron-ore consumption decreased 11 percent in response to a smaller demand for pig iron and to serious coal and steel strikes. The 1949 decline in call for the nonferrous metals, copper, aluminum, lead, and zinc was remarkably uniform, all between 13 and 17 percent. The decrease in consumption of tin was somewhat sharper; this is partly a result of 1949 being the first year in which tin-plate production by the electrolytic method (requiring less than half as much tin) exceeded that by the hot-dip method.

United States industry is fully self-sufficient in coal, sulfur, cement, phosphate, potash, molybdenum, and magnesium, and is nearly so in iron and petroleum. On the other hand, most of the aluminum, uranium, tin, mercury, and cobalt needed by the Nation in 1949 was from foreign ores, and the dependency was at least 90 percent for such vital materials as manganese, chromium, nickel, industrial diamonds, sheet mica, asbestos, radio-grade quartz, tantalum, columbium, and beryllium. An exact numerical measurement of self-sufficiency is not available because of incomplete data on stocks and because of censorship of national stockpile inventories. However, the ratio of production to actual consumption or to apparent consumption, as shown for various minerals in 1949 in table 6, is a reasonable indication of self-sufficiency. If secondary metals are taken into account, United States self-sufficiency of antimony, platinum, and tin is raised substantially, but there is slight improvement of the aluminum, zinc, and nickel position.

943785—51——2

TABLE 6.—Consumption and self-sufficiency of the United States in various mineral products in 1949

Mineral product [1] and unit	Production			Consumption			Self-sufficiency (percent) [3]	
	Primary	Secondary [2]	Total	Primary	Secondary	Total	Primary	Total
Aluminum, refined ... short tons	[4] 241,385	44,596	285,981	[5] 635,956	[5] 44,596	[5] 680,552	33	42

[1] Production of metals, unless otherwise specified, is recoverable metal content of ore mined; production of metals described as refined is refinery production from domestic ores. Consumption of metals, unless otherwise specified, is of refined metal from domestic and foreign ores.
[2] From old scrap only.
[3] Ratio of production to consumption.
[4] Estimate for metal from domestic ores only.
[5] Apparent consumption.
[6] Less than 0.5 percent.

STOCKS

Bituminous-coal stocks held by consumers and retail coalyards decreased 35 percent during 1949, reaching a level approximating that in 1944-47. Anthracite stocks in the hands of producers were virtually unchanged.

Industry inventories of pig iron and of primary lead in all forms and producers' stocks of aluminum metal increased 3, 27, and 121 percent, respectively, to postwar highs. Although industry holdings of slab zinc gained 50 percent during 1949, the year-end mark was 35 percent below that of December 1946. One metal whose stocks declined was refined copper (producers and fabricators) 7 percent.

Cement mills during 1949 added 33 percent to the number of barrels on hand, resulting in a year-end inventory greater than at any comparable time since 1945. Producers' stocks of sulfur, phosphate rock, and potash declined 4, 23, and 25 percent, respectively. In 1943-49, sulfur stocks fell 39 percent, as production was unable to keep up with demand; this is partly a result of depletion of unmined reserves.

PRICES

The postwar surge in mineral prices as a whole leveled off during 1949, when the rise was less than 1 percent, according to the Bureau of Mines index of producers' sales of 24 minerals,[8] representing all but a few percent of the total value of United States mineral production. Among the three major mineral groups, fuels in 1949 continued to be the most costly (compared with 1940) despite a 2-percent price decline during the year. This group decline was counteracted by price increases of 3 percent for other nonmetallic minerals and of 7 percent for metals. The most notable individual price increases were for molybdenum concentrates (20 percent) and pig iron (14 percent); the molybdenum price change was the first since 1938. The sharpest price decreases in 1949 were for natural gasoline (23 percent) and lead (12 percent), although the natural-gasoline price remained above the 1947 level.

TABLE 7.—Weighted average price index of 24 major mineral commodities, 1943–48

[1940=100]

Group	1943	1944	1945	1946	1947	1948	1949 [1]
Minerals (all groups)	119.7	122.7	125.3	138.7	168.5	203.5	205.1
Mineral fuels	122.6	126.9	129.5	145.3	181.7	227.2	222.6
Nonmetals (other than fuels)	112.0	113.7	115.4	122.2	134.6	146.0	150.4
Metals [2]	117.1	118.0	120.9	132.4	156.6	189.5	193.0

[1] Preliminary.
[2] Includes bonus payments on copper, lead, and zinc, 1943-47.

[8] Fuels—bituminous coal and lignite, natural gas, natural gasoline and cycle products, and crude petroleum. Nonmetals—cement, clay, lime, phosphate rock, natural pigments, potash, salt, sand and gravel, stone, and native sulfur. Metals (refined)—aluminum, copper, ferro-alloys, gold, pig iron, lead, magnesium, molybdenum concentrates, silver, and zinc.

Wholesale prices of commodities as a whole declined 6 percent, as reflected in the Bureau of Labor Statistics index (1926=100) of 155.0 in 1949 and 165.1 in 1948. This index includes the mineral-products components shown in table 8.

TABLE 8.—Wholesale price indexes of mineral-product groups, 1947–49

[Bureau of Labor Statistics, 1926=100]

Product	1947	1948	1949	Product	1947	1948	1949
FUELS				NONMETALLICS			
Anthracite	117.6	[1] 130.9	137.0	Brick and tile	140.0	156.3	161.7
Bituminous coal	157.6	187.0	192.0	Cement	115.7	[1] 130.4	133.8
Coke	166.6	207.1	222.2	Chemicals	118.7	[1] 126.7	117.4
Petroleum products	90.2	122.1	112.2	Fertilizer materials	105.6	116.1	119.7

METALS							
Iron and steel	133.7	[1] 155.1	165.7				
Nonferrous metals	140.3	157.5	144.3				
Structural steel	134.5	163.7	179.3				

[1] Revised figure.

EMPLOYMENT, WAGES, AND SAFETY

Employees in the mining industry in 1949 averaged 917,000, 7 percent less than in the preceding year but 5 percent more than in 1946, according to the Bureau of Labor Statistics. Earnings per full-time employee in the mining industry in 1949 averaged $3,204, a 5-percent cut from 1948 but a 3-percent gain over 1947.

TABLE 9.—Number of employees and average earnings in mining and related manufacturing industries, 1947–49

[U. S. Bureau of Labor Statistics]

Industry	Number of full-time equivalent employees (thousands)			Average annual earnings per full-time employee		
	1947 [1]	1948 [1]	1949	1947 [1]	1948 [1]	1949
Bituminous coal and lignite	429	452	399	$3,212	$3,383	$2,922
Anthracite	80	81	77	3,125	3,420	2,896
Petroleum and natural gas	235	255	250	3,157	3,584	3,736
Metals	99	101	95	3,000	3,327	3,411
Nonmetallic minerals	95	97	96	2,663	2,928	3,031
Total mining	938	986	917	3,113	3,387	3,204
Iron and steel products [2]	1,863	1,872	1,661	3,063	3,360	3,390
Nonferrous metal products	482	476	425	2,969	3,248	3,268
Products of petroleum and coal	228	235	229	3,610	4,072	4,179
Stone, clay, and glass products	503	523	487	2,672	2,925	3,012

[1] Revised figures. [2] Including ordnance.

The average number of days worked by the mining and metallurgical industries (exclusive of petroleum and steelmaking) was 207 (preliminary figure) in 1949, compared with 249 in 1948 and 256 in 1947, according to the Bureau of Mines. Idleness from work stoppages in the mineral industries, particularly the coal industry, in

1949 constituted nearly 40 percent of the total man-days lost by stoppages in all industries, the United States Department of Labor reported. Fewer employees working fewer days resulted in a 20-percent decline in man-hours worked in the mineral industries in 1949 compared with 1948.

Mines in the United States were less hazardous in 1949 than ever before. The nonfatal injury frequency rate in mining and metallurgical industries improved from 48.7 per million man-hours in 1948 to 45.5 in 1949. The number of fatalities, partly due to shorter exposure, declined from 1,227 in 1948 to 772 in 1949. A report [9] was published on the causes of mine accidents and on progress through the years in preventing such accidents.

FOREIGN TRADE [10]

Imports of mineral products were valued at 2.5 billion dollars in 1949, compared with 3.6 in 1948 and 3.2 in 1947. Exports of mineral products were valued at 2.3 billion dollars in 1949, 2.8 in 1948, and 3.0 in 1947. The leading mineral imports in 1949 were gold, petroleum, copper, tin, and lead. The principal mineral exports in 1949 were iron (including manufactures), petroleum and products, coal, copper, and gold.

In terms of tonnage, four-fifths of all the imports and exports of the United States in 1949 were minerals. This proportion is derived from table 12 by comparing the mineral entries with the total minus "undistributed." Petroleum and its products constituted, on a weight basis, 52 percent of total imports and 17 percent of total exports. Coal represented 34 percent of all exports.

Total mineral products				3,029,238	2,779,525	2,322,792

[1] Less than 1 ton.
[2] Less than $1,000.
[3] Quantity excludes and value includes certain copper manufactures for which weight is not recorded, as follows: 1947—$2,580,974; 1948—$2,249,857; 1949—$1,655,349.
[4] Quantity excludes and value includes hardware and certain other brass and bronze manufactures for which weight is not recorded, as follows: 1947—$8,655,453; 1948—$6,337,009; 1949—$5,499,295.
[5] Quantity excludes and value includes advanced manufactures for which weight is not recorded, as follows: 1947—$87,570,810; 1948—$57,376,497; 1949—$52,410,757.
[6] Amounts stated do not include fuel or bunker coal loaded on vessels engaged in foreign trade, which aggregated 1,689,328 short tons in 1947, 1,057,118 tons in 1948, 874,029 tons in 1949; corresponding values not available.
[7] Exclusive of 102,179 tons valued at $1,010,820 exported to Austria as a part of the Army Civilian Supply Program.
[8] Wax, manufactured asphalt, petroleum coke, petroleum jelly, etc.
[9] Excludes 198,723 barrels valued at $839,916 exported to Korea under the Army Civilian Supply Program.
[10] Excludes 996,430 short tons valued at $10,648,643 exported under the Army Civilian Supply Program.
[11] Excludes 22,075 short tons valued at $1,324,521 exported to Japan under the Army Civilian Supply Program.
[12] Excludes 96,479 short tons valued at $2,347,679 exported under the Army Civilian Supply Program.
[13] Quantity not recorded in tons.
[14] Excludes 599 short tons valued at $30,589 sent to Japan under the Army Civilian Supply Program.

TABLE 12.—Imports and exports of the United States, by commodities, 1948–49, in millions of long tons (shipping weight)

[U. S. Departments of Commerce and of the Army]

Commodity	Imports[1]				Exports[1]			
	1948	1949			1948	1949		
	Total	Seaboard	Great Lakes	Total	Total	Seaboard	Great Lakes	Total
Fuels:								
Anthracite	--------	--------	--------	--------	1.5	1.2	--------	1.2
Bituminous coal	--------	--------	--------	--------	34.3	10.3	10.4	20.7
Coke	--------	--------	--------	--------	--------	--------	.1	.1
Petroleum and products	29.0	35.8	--------	35.8	13.0	9.8	1.1	10.9
Metals:								
Bauxite	2.8	2.9	--------	2.9	--------	--------	--------	--------
Chromite	1.4	1.1	--------	1.1	--------	--------	--------	--------
Iron ore	5.9	5.4	1.7	7.1	2.9	--------	2.1	2.1
Manganese ore	1.3	1.5	--------	1.5	--------	--------	--------	--------
Steel-mill products	--------	--------	--------	--------	3.2	3.4	--------	3.4
Nonmetallic minerals:								
Nitrogenous fertilizer materials	.7	.7	--------	.7	--------	--------	--------	--------
Phosphatic fertilizer materials	--------	--------	--------	--------	.6	1.0	--------	1.0
Sand and gravel	.3	--------	.3	.3	--------	--------	--------	--------
Sulfur	--------	--------	--------	--------	1.2	1.3	--------	1.3
Nonmetallic minerals, n. e. s.	2.9	2.6	--------	2.6	.8	--------	.8	.8
Rubber	.8	.7	--------	.7	--------	--------	--------	--------
Wood and paper[1]	2.4	1.1	1.0	2.1	1.0	.9	--------	.9
Cotton (unmanufactured)	--------	--------	--------	--------	.7	1.3	--------	1.3
Food and feed products[1]	7.8	7.5	.9	8.4	8.6	7.7	.6	8.3
Undistributed[1]	4.9	5.5	.4	5.9	11.1	11.6	.6	12.2
Total	60.2	64.8	4.3	69.1	78.9	48.5	15.7	64.2

[1] If a commodity is only a minor factor in either seaboard or Great Lakes trade, the tonnage for that area is excluded from the commodity total and included with "undistributed." The totals shown for the commodity groups "wood and paper" and "food and feed products" represent only the sum of major items; minor items are included with "undistributed."

INCOME AND TAXATION

Mining enterprises in the United States earned 1,216 million dollars in 1949, compared with 1,814 in 1948, 1,355 in 1947, and 681 in 1946 (revised figures).[11] These earnings are after wages, salaries, inventory adjustment, and interest but before depletion charges and taxes. Federal and State taxes on total corporate income in the mining industry ranged between 27 and 34 percent in 1942–48 but dropped to 23 percent in 1949. Of the five major mining groups, the nonmetallics industry paid the highest tax rate (32 percent) in 1949 and oil and gas producers the smallest (19 percent). The average rate on all corporations in the United States was 38 percent.

TABLE 13.—Income and corporation taxes of mining and related manufacturing enterprises in the United States in 1949, in millions of dollars [1]

[U. S. Department of Commerce]

Industry	Corporate income				Income of unincorporated enterprises	Grand total
	Taxes (Federal and State)	Dividend payments	Undistributed	Total		
Bituminous coal and lignite	66	53	128	247	46	293
Anthracite	4	8	7	19	4	23
Petroleum and natural gas	87	125	236	448	139	587

Nonmetallic minerals	38	37	44	119	12	131
Total mining	235	305	468	1,008	208	1,216
Iron and steel products [2]	761	434	683	1,878	50	1,928
Nonferrous metal products	117	115	77	309	23	332
Products of petroleum and coal	396	538	793	1,727	3	1,730
Stone, clay, and glass products	182	122	179	483	40	523

[1] Before deduction of depletion charges.
[2] Including ordnance.

[11] Office of Business Economics, National Income and Product of the United States: Survey of Current Business, vol. 30, No. 7, July 1950, pp. 5–35.

MINERAL POLICY DEVELOPMENTS

Economic Cooperation with Europe.—Commodity procurements authorized by the Economic Cooperation Administration by the end of 1949 for shipment to western Europe totaled 7.4 billion dollars. Of this amount, 32 percent was for food and feed, 27 percent for mineral products, 25 percent for textiles, forest products, tobacco, and chemicals, and 16 percent for machinery and vehicles. The 1,985 million dollars authorized for mineral products comprised 775 for petroleum and products, 572 for nonferrous metals, 281 for coal, 245 for iron and steel, and 112 for nonmetallic minerals including fertilizer. These shipments helped the participating Europeans to boost their industrial production in the final quarter of 1949 to a high 20 percent above the prewar level. Besides raw materials, the war-devastated European economy needed replacement, modernization, and expansion of its productive facilities. Of the industrial projects planned at the end of 1949, those with an aggregate cost of 1.4 billion dollars were approved by the Economic Cooperation Administration and will be financed by that agency to the extent of about one-fourth the cost. More than three-fourths of the approved industrial projects are for mining or refining minerals. The amount actually authorized by ECA for industrial projects as of December 31, 1949, was 188 million dollars, of which 93 were for iron and steel production, 12 for petroleum refining, 8 for coal mining, 7 for iron mining, and 2 each for potash mining, aluminum refining, and cement production.

Each participating country places in a counterpart fund local currency equal to the ECA dollar grants. Five percent of the counterpart funds is reserved for the United States to use for informational activities, ECA administrative expenses, and purchase of strategic materials. In this manner the United States acquired by the end of 1949 industrial diamonds, bauxite, graphite, and cryolite worth 13 million dollars. Such purchases were limited by the relatively small surplus of strategic materials in participating countries. ECA committed in 1948 and 1949 the equivalent of 6 million dollars in counterpart funds for development of strategic materials under contracts providing for repayment in materials for the United States National Stockpile. The principal project involved was modernization and expansion of lead-zinc mining at Bou Beker, French Morocco. Other projects included exploring for minerals in British African territories and developing mining of lead-zinc in Sweden, cobalt in Northern Rhodesia, and kyanite in Kenya.

American Investments Abroad.—United States residents had investments abroad at the close of 1948 (in firms in which they held at least 25 percent of the stock) totaling 11.4 billion dollars. Of this amount, 27 percent was in the petroleum industry and 10 percent represented other mining and smelting enterprises, according to the Department of Commerce. Capital movements abroad (exclusive of reinvested earnings) in 1946–48 were 1,650 million dollars, three-fourths of which was for the petroleum industry, notably in Saudi Arabia and Venezuela. These investments were stimulated primarily by the increasing world demand for oil and by the availability of large proven reserves of oil abroad. Furthermore, Venezuela instituted a requirement that 10 percent of its crude petroleum output be refined within the country; this led to the construction of American-owned refineries there.[12]

TABLE 14.—Value of private United States direct investments[1] abroad, by industry division and area, on Dec. 31, 1948, in millions of dollars

[U. S. Department of Commerce]

Industry division	Canada	Latin American Republics	OEEC countries		Other Europe	Other countries	Total
			Home	Dependencies			
Petroleum	278	1,376	369	391	68	565	3,047
Other mining and smelting	501	433	65	42	82	24	1,147
Manufacturing	1,573	676	1,035	17	113	189	3,603
Other industries	835	1,726	552	90	80	299	3,582
Total	3,187	4,211	2,021	540	343	1,077	11,379

[1] Direct investments comprise foreign branches of American companies, and foreign corporations in which United States residents hold 25 percent or more of the voting stock.

Stockpiling.—The objective of the National Stockpile is to have on hand a supply of materials sufficient to bridge the gap between wartime requirements and available wartime supply. As envisaged at the end of 1949, such stocks would cost $3,773 million. Of this amount, $1,149 million represented materials on hand, $416 million was obligated for materials on order, and $1,208 million (a third of which was appropriated) was unexpended. The Munitions Board stated that some materials could not be stockpiled fast enough, because world production was too low to meet current industrial needs and still leave a margin to be reserved for future emergency.

[12] Abelson, Milton, Private United States Direct Investments Abroad: Survey of Current Business, vol. 29, No. 11, November 1949, pp. 18–23.

The Munitions Board 1948 list of strategic minerals subjected to stockpiling was presented in Minerals Yearbook, 1948, pages 12–13. The 1949 version of the list added to group I (materials acquired by purchase or by transfer from Government agencies) aluminum metal, chemical-grade chromite, and crocidolite asbestos. At the same time the following minerals, all formerly in group II (strategic but not recommended for stockpile purchase), were dropped from the strategic list: Barite, English chalk, emery, optical glass, iron ore, petroleum and products, radium, and scrap iron and steel. The materials remaining in group II were to be stockpiled but only through transfer of Government-owned surpluses.

Several papers[13] on stockpile policies were published.

Mining Law.—The Commission on Organization of the Executive Branch of the Government presented evidence of needed revisions in mining law and listed recommendations.[14]

TECHNOLOGY

Geophysical exploration was employed to locate a lead-zinc deposit at Silver City, N. Mex.,[15] and to search for asbestos in Maine.[16] Further progress was made in jet-piercing drilling of traprock.[17] Bureau of Mines engineers in 1945–48 surveyed water pools in Pennsylvania anthracite mines.[18] In the interest of mine safety, reports were made on practices in dredging and hydraulic operations,[19] accidents in Lake Superior iron mines,[20] characteristics of explosives,[21] and permissible mine equipment.[22] Intensive work continues on iron-ore beneficiation[23] and on hydrogenation of coal to yield liquid fuels.[24] The Bureau of Mines cooperated with the American Gas Association in investigating prevention of "freezing" of natural-gas transmission lines.[25]

WORLD REVIEW

World outputs of cement, natural gas, and phosphate rock were at all-time highs in 1949, and those of iron, gold, and lead were somewhat greater than in 1948. However, production of petroleum, bauxite, and native sulfur were 1 to 2 percent less than in 1948, and that of coal and copper 4 to 5 percent less.

Western Hemisphere.—The Canadian iron ore situation [26] and a review of the Dominion's mining laws [27] were published. Coal reserves on the Pacific Coast of Mexico were estimated at 2 to 4 million tons.[28] The chief problem in use of Brazilian iron ore continued to be transportation.[29] Reports were made on the manganese (Serra do Navio district)[30] and coal [31] resources of Brazil. Coal in Chile also was studied.[32] The July 1949 issue of Engineering and Mining Journal contained brief articles on iron ore in Labrador and Venezuela and on copper, lead, and zinc in Newfoundland, Peru, Chile, and Argentina.

Tin [4] thousand long tons	158	37	23	169	36	21
Zinc	1,692	715	42	1,810	739	41

[1] Data not available.
[2] 246 carats in 1948–49.
[3] Less than 0.5 percent.
[4] Exclusive of U. S. S. R.
[5] 393 tons.
[6] 5 tons.
[7] 68 tons.

Europe and Africa.—Half of the iron smelted by the United Kingdom is from its own ores, which contain only 19 to 33 percent Fe.[33] The European economy benefited from increased output of Polish coal.[34] The mineral resources of the United Kingdom, Greece, Norway, Sweden, and Finland were described in 1949 in Engineering and Mining Journal (January and March issues), and the same magazine (July issue) reported the progress of lead-zinc mining in French Morocco and South-West Africa. The accident rate at South African gold mines has been reduced.[35] The occurrence of uranium, despite its low concentration, in Witwatersrand gold ores is important because of the magnitude of operations.

Asia.—The Matsuo sulfur mine in Japan is in a deposit comparable in size to the Rio Tinto orebody in Spain.[36] Safety conditions in Japanese coal mines were examined.[37] Descriptions were published of the aluminum industry in Japan, Korea, Manchuria, and Formosa,[38] and of tin mining in Malaya[39] and Indonesia.[40]

Reserves.—Only North America and Europe have great unmined reserves of coal and iron together, as shown in table 16. North America, unlike Europe, shares with Asia most of the known petroleum resources. The Western Hemisphere is notably deficient in manganese and tin. At least one-fourth of the specified major nonferrous-metal reserves are in these continents: North America, copper, lead, and zinc; South America and Africa, copper; Europe, none; Asia, bauxite and tin; Oceania, lead.

Statistical Summary of Mineral Production

By John Hozik and K. Joyce D'Amico

GENERAL SUMMARY

PRESENTATION of the mineral statistics in this report represents a departure from the procedure followed in earlier years. The basis of the statistical series comprising the State production tables was little changed; but application of that basis to the national production tables, in the interest of uniformity, entailed a major revision in the United States totals. A detailed explanation of the new and old statistical series follows.

Coverage.—Statistics used in this chapter to derive total mineral production of the United States and of individual States represent primary products only and exclude products from scrap. The figures on the new basis given in table 1 for 1947–49 pertain to production exclusively from domestic mines; statistics on the old basis in some instances include mineral products made from material of foreign origin.

The value of United States mine output, as now constituted, is limited geographically to the 48 States and the District of Columbia. Heretofore, the value of United States mineral output included production in Alaska, Hawaii, Philippine Islands (through 1945), and Puerto Rico, but no statistics were collected for other United States possessions. In this report separate data for the Territories of Alaska and Hawaii and for the possessions of the United States are given in tables 6 and 7. A summary of mineral output in States, Territories, and possessions appears in table 8. Mineral waters are excluded from the new 1947–49 series, inasmuch as the Standard Commodity Classification considers mineral water a beverage rather than a mineral product.

Stage of Production Measured.—The aim of this report is to present national and State total values representing mine output (or the output of concentrating mills at or near the mine). The value of the fuels, nearly all the nonmetallic minerals, and iron are so measured at the mine, but comparable data for most nonferrous metals are not available. The mineral products valued at the refined stage of production rather than at the mine are cement, lime, antimony, copper, gold, lead, mercury, silver, tin, and zinc.

Revisions in State Tables.—The State tables for 1947–49 in this report differ in basis from preceding editions in that the heavy clay-products statistical series has been replaced by a clay series, and estimates have been added for natural carbon dioxide and gem stones.

Revisions in National Tables.—The following changes in the basis of the 1947–49 United States tables were made for comparability with the State tables: Natural gas is valued at wells rather than at points of consumption. The clay series is modified to replace heavy clay products. An estimate for natural carbon dioxide was added. The series for aluminum, pig iron, magnesium, nickel, and refined platinum-group metals were replaced, respectively, by bauxite, iron ore, magnesium chloride, nickel ore, and crude platinum-group metals. Antimonial lead, ferro-alloys, mineral pigments, and byproduct sulfuric acid were deleted to eliminate duplication, and arsenic, bismuth, cadmium, germanium, indium, radium, selenium, tellurium, and thallium were omitted because they are smelter and refinery byproducts that seldom if ever affect (except indirectly) the price paid for the nonferrous ores in which they are contained in low concentrations. The quantities of copper, gold, lead, silver, and zinc are mine outputs rather than smelter, refinery, or mint production; the unit values applied to these mine volumes to derive values, however, continue to be the average weighted price of all grades of primary refined metal sold by producers.

Although the new basis that applies to 1949 was revised back only 2 years, it is intended to revise earlier years so that a long-term comparable series will be available.

Units of Measurement.—In expressing quantities of minerals, the Bureau of Mines has adopted the weight or volume units commonly employed by each individual industry. The unit of value is the United States dollar. No adjustment is made for fluctuations in the purchasing power of the dollar.

TABLE 1.—Value of mineral production in the United States, 1880–1945 (5-year intervals) and 1946–49

Year	Nonmetallic			Metallic	Grand total
	Fuels	Other	Total		
1880	$120, 241, 000	$56, 341, 000	$176, 582, 000	$190, 881, 000	$367, 463, 000
1885	183, 075, 000	61, 758, 000	244, 833, 000	174, 718, 000	419, 551, 000
1890	230, 962, 000	80, 530, 000	311, 492, 000	303, 937, 000	615, 429, 000
1895	268, 438, 000	125, 720, 000	394, 158, 000	248, 533, 000	642, 691, 000
1900	406, 376, 000	188, 328, 000	594, 704, 000	514, 232, 000	1, 108, 936, 000
1905	602, 258, 000	318, 722, 000	920, 980, 000	702, 785, 000	1, 623, 765, 000

Vanadium ore and concentrates....pounds, V content..	2,117,962	1,285,026	(11)	(11)	(11)	(11)
Zinc....Zn content..	637,683	153,112,356	629,955	167,973,567	593,201	148,912,878
Other metals [13]....		3,876,513		10,467,595		6,670,946
Total metals....		1,084,000,000		1,219,000,000		1,101,000,000
Grand total mineral production....		9,610,000,000		12,273,000,000		10,554,000,000

[1] Production as measured by mine shipments or mine sales (including consumption by producers), except that fuels and the following additional minerals are strictly production: Gypsum, iodine, magnesite, pyrites, antimony, bauxite, and mercury. The 1949 figures for natural gas, natural-gas liquids, and petroleum are preliminary. Excludes uranium ores.

[2] Includes small quantity of anthracite mined in States other than Pennsylvania.

[3] Excludes sharpening stones, which are included with "Other nonmetallic minerals."

[4] Weight not recorded.

[5] Revised figure.

[6] Excludes clays sold or used for cement as follows: 1947—5,336,492 short tons, $2,987,424; 1948—6,362,459 tons, $4,320,266; 1949—6,676,134 tons, $4,572,797.

[7] Value included with "Other nonmetallic minerals."

[8] Excludes production from Wyoming, value for which is included with "Other nonmetallic minerals."

[9] Excludes abrasive stone, bituminous limestone, bituminous sandstone, and ground soapstone, all included elsewhere in table. Also excludes limestone for cement and lime.

[10] Comprises andalusite, aplite, brucite, diatomite, dumortierite (1949), epsom salts from serpentine (1947) and epsomite (1949), iodine, perlite, sharpening stones, sodium carbonate (Wyoming 1948), and minerals indicated by footnote 7.

[11] Value included with "Other metals."

[12] Less than ½ ton.

[13] Comprises magnesium chloride for magnesium metal, zirconium concentrates, and minerals indicated by footnote 11.

TABLE 3.—Minerals produced in continental United States and principal producing States in 1949

Rank in value	Mineral	Principal producing States: In order of quantity	Principal producing States: In order of value
	Abrasive stone:		
69	Grindstones and pulpstones	Ohio, West Virginia, Washington	Rank same as for quantity.
82	Millstones	Not available	North Carolina, Virginia.
74	Pebbles (grinding)	Minnesota, Wisconsin, Texas, North Carolina	Rank same as for quantity.
77	Tube-mill liners (natural)	Minnesota, North Carolina, Wisconsin	Minnesota, Wisconsin, North Carolina.
86	Andalusite	Nevada	Rank same as for quantity.
50	Antimony ore and concentrates	Idaho, Nevada, Oregon, Washington	Do.
67	Aplite	Virginia	Do.
41	Asbestos	Vermont, Arizona, Georgia, California	Do.
31	Asphalt (native)	Texas, Kentucky, Alabama, Oklahoma	Texas, Kentucky, Utah, Alabama.
30	Barite (crude)	Arkansas, Missouri, Nevada, Georgia	Arkansas, Missouri, Georgia, Nevada.
27	Bauxite	Arkansas, Georgia, Alabama	Rank same as for quantity.
72	Beryllium concentrates	New Hampshire, Colorado, South Dakota, New Mexico	Do.
24	Boron minerals	California	Do.
22	Bromine	Texas, Michigan, California, West Virginia	Texas, Michigan, West Virginia, California.
66	Brucite	Nevada	Rank same as for quantity.
39	Calcium-magnesium chloride	Michigan, West Virginia, California, Ohio	Michigan, California, West Virginia, Ohio.
64	Carbon dioxide (natural)	California, Utah, New Mexico, Oregon	California, Oregon, Washington, Utah.
3	Cement	Pennsylvania, California, Texas, New York	Rank same as for quantity.
81	Chromite	California	Do.
13	Clays	Ohio, Pennsylvania, California, Illinois	Georgia, Pennsylvania, Ohio, Missouri.
2	Coal:		
	Bituminous	West Virginia, Pennsylvania, Kentucky, Illinois	Rank same as for quantity.
	Lignite	North Dakota, Texas, Montana, South Dakota	North Dakota, Montana, South Dakota, Texas.
	Pennsylvania anthracite	Pennsylvania	Rank same as for quantity.
70	Cobalt	Pennsylvania	Do.
8	Copper	Arizona, Utah, Montana, New Mexico	Do.
29	Diatomite	California, Oregon, Nevada, Washington	Do.
85	Dumortierite	Nevada	Do.
75	Emery	New York	Do.
83	Epsomite	Washington	Do.
44	Feldspar (crude)	North Carolina, Colorado, Virginia, South Dakota	North Carolina, Colorado, New Hampshire, Virginia.
25	Fluorspar	Illinois, Kentucky, Colorado, New Mexico	Rank same as for quantity.
57	Garnet (abrasive)	New York, Idaho	Do.
61	Gem stones	Not available	Oregon, California, Washington, Texas.
15	Gold	South Dakota, California, Utah, Nevada	Rank same as for quantity.

TABLE 8.—Minerals produced in continental United States and principal producing States in 1949—Continued

Rank in value	Mineral	Principal producing States: In order of quantity	Principal producing States: In order of value
60	Graphite:		
	Amorphous	Rhode Island	Rank same as for quantity.
	Crystalline	Texas, Alabama	Do.
21	Gypsum (crude)	Michigan, New York, Iowa, Texas	Do.
55	Helium	Texas	Do.
49	Iodine	California	Do.
4	Iron ore (usable)	Minnesota, Michigan, Alabama, Utah	Minnesota, Michigan, Alabama, New York.
63	Kyanite	Virginia, South Carolina, Georgia	Rank same as for quantity.
11	Lead	Missouri, Idaho, Utah, Arizona	Do.
14	Lime (open-market)	Ohio, Pennsylvania, Missouri, Alabama	Ohio, Pennsylvania, Missouri, West Virginia.
66	Lithium minerals	South Dakota, California	California, South Dakota.
46	Magnesite (crude)	Washington, Nevada, Texas, California	Rank same as for quantity.
45	Magnesium chloride (for magnesium metal)	Texas	Do.
34	Magnesium compounds from sea water and brines (except for metal).	California, Michigan, New Jersey, Texas	Michigan, California, New Jersey, Texas.
33	Manganese ore	Montana, Arkansas, California, Virginia	Montana, Arkansas, Arizona, Tennessee.
37	Manganiferous ore	Minnesota, New Mexico, Arkansas, Montana	Minnesota, New Mexico, Montana, Arkansas.
48	Manganiferous residuum	New Jersey	Rank same as for quantity.
	Marl:		
71	Calcareous	Virginia, Indiana, Wisconsin, West Virginia	Virginia, Indiana, Nevada, West Virginia.
68	Greensand	New Jersey	Rank same as for quantity.
53	Mercury	California, Nevada, Oregon	Do.
52	Mica	North Carolina, Colorado, Pennsylvania, South Dakota	Do.
	Scrap	North Carolina, Colorado, Pennsylvania, South Dakota	Do.
	Sheet	North Carolina, New Hampshire, Georgia, South Dakota	North Carolina, New Hampshire, South Dakota, Georgia.
20	Molybdenum concentrates	Utah, Colorado, New Mexico, Arizona	Colorado, Utah, New Mexico, Arizona.
6	Natural gas	Texas, Louisiana, California, Oklahoma	Texas, California, West Virginia, Louisiana.
5	Natural-gas liquids:		
	Natural gasoline and cycle products	Texas, California, Louisiana, Oklahoma	Rank same as for quantity.
	LP-gases	Texas, California, Oklahoma, Louisiana	Do.
76	Olivine	North Carolina, Washington	Do.
51	Peat	New Jersey, Ohio, Minnesota, Florida	Ohio, New Jersey, Michigan, Maine.
56	Perlite (crude)	Nevada, New Mexico, Colorado, Oregon	Nevada, Oregon, New Mexico, Colorado.
1	Petroleum (crude)	Texas, California, Louisiana, Oklahoma	Rank same as for quantity.
17	Phosphate rock	Florida, Tennessee, Idaho, Montana	Florida, Tennessee, Montana, Idaho.
79	Platinum-group metals (crude)	California	Rank same as for quantity.
18	Potassium salts	New Mexico, California, Utah, Michigan	Do.
43	Pumice and pumicite	New Mexico, California, Oregon, Idaho	Do.

38	Pyrites	Tennessee, Virginia, Montana, California	Tennessee, Virginia, California, Montana.
59	Quartz from pegmatites and quartzite	Washington, North Carolina, Connecticut, Wisconsin	Washington, North Carolina, Connecticut, Arizona.
16	Salt (common)	Michigan, New York, Ohio, Louisiana	Michigan, New York, Louisiana, Kansas.
9	Sand and gravel	California, Michigan, New York, Illinois	California, New York, Illinois, Pennsylvania.
32	Sand and sandstone (ground)	Illinois, New Jersey, West Virginia, Ohio	Illinois, West Virginia, New Jersey, Ohio.
80	Sharpening stones	Arkansas, Indiana, Ohio, New Hampshire	Rank same as for quantity.
19	Silver	Idaho, Utah, Montana, Arizona	Do.
23	Slate	Pennsylvania, Vermont, New York, Maryland	Pennsylvania, Vermont, New York, Virginia.
36	Sodium carbonate (natural)	California	Rank same as for quantity.
40	Sodium sulfate (natural)	California, Texas, Wyoming	Do.
7	Stone	Pennsylvania, Ohio, Illinois, Michigan	Pennsylvania, Ohio, Illinois, New York.
12	Sulfur (refined)	Texas, Louisiana	Rank same as for quantity.
73	Sulfur ore for direct agricultural use	Wyoming, California, Nevada, Colorado	Do.
26	Talc, pyrophyllite, and ground soapstone	New York, North Carolina, California, Vermont	New York, California, North Carolina, Vermont.
78	Tin concentrates	Colorado	Rank same as for quantity.
	Titanium concentrates:		
28	Ilmenite	New York, Florida, North Carolina, Virginia	New York, Florida, Virginia, North Carolina.
58	Rutile	Florida, Virginia	Rank same as for quantity.
87	Topaz (industrial)	South Carolina	Do.
54	Tripoli	Missouri, Illinois, Pennsylvania	Do.
35	Tungsten concentrates	California, North Carolina, Nevada, Colorado	California, Nevada, North Carolina, Colorado.
42	Vanadium concentrates	Colorado, Utah, Idaho, Arizona	Rank same as for quantity.
47	Vermiculite	Montana, South Carolina, North Carolina, Colorado	Do.
84	Wollastonite	New York	Do.
10	Zinc	Idaho, Arizona, Montana, New Jersey	Idaho, Arizona, New Jersey, Montana.
62	Zirconium concentrates	Florida	Rank same as for quantity.

TABLE 4.—Value of mineral production in continental United States, 1947–49, by States, and principal minerals produced in 1949

State	1947	1948	1949 Value	1949 Rank	1949 Percent of United States total	1949 Principal minerals in order of value
Alabama	$158,275,000	$183,797,000	$143,879,000	17	1.36	Coal, iron ore, cement, stone.
Arizona	186,081,000	200,358,000	181,095,000	14	1.72	Copper, zinc, lead, silver.
Arkansas	90,857,000	122,089,000	109,276,000	23	1.04	Petroleum, coal, bauxite, natural-gas liquids.
California	843,413,000	1,146,411,000	1,074,416,000	2	10.18	Petroleum, natural-gas liquids, natural gas, cement.
Colorado	102,449,000	128,861,000	141,165,000	18	1.34	Petroleum, coal, zinc, molybdenum concentrates.
Connecticut	3,863,000	4,484,000	4,887,000	45	.05	Stone, sand and gravel, lime, clays.
Delaware	340,000	408,000	335,000	48	----------	Sand and gravel, stone, clays.
District of Columbia	61,000	64,000	63,000	49	----------	Clays.
Florida	45,847,000	53,664,000	54,998,000	28	.52	Phosphate rock, cement, stone, sand and gravel.
Georgia	32,009,000	36,103,000	35,508,000	34	.34	Clays, stone, cement, sand and gravel.
Idaho	66,822,000	79,128,000	64,292,000	27	.61	Lead, zinc, silver, gold.
Illinois	425,380,000	521,038,000	450,008,000	7	4.26	Coal, petroleum, stone, cement.
Indiana	133,862,000	161,950,000	140,676,000	19	1.33	Coal, petroleum, cement, stone.
Iowa	31,023,000	35,955,000	37,458,000	31	.35	Cement, stone, coal, sand and gravel.
Kansas	265,061,000	361,180,000	335,699,000	9	3.18	Petroleum, cement, natural gas, coal.
Kentucky	426,101,000	504,080,000	375,400,000	8	3.56	Coal, petroleum, natural gas, stone.
Louisiana	404,779,000	604,198,000	616,245,000	5	5.84	Petroleum, natural-gas liquids, natural gas, sulfur.
Maine	5,784,000	8,094,000	6,742,000	44	.06	Cement, stone, sand and gravel, slate.
Maryland	23,201,000	25,002,000	20,461,000	37	.19	Sand and gravel, cement, coal, stone.
Massachusetts	10,576,000	12,583,000	12,449,000	40	.12	Stone, sand and gravel, lime, clays.
Michigan	166,634,000	202,885,000	200,447,000	12	1.90	Iron ore, petroleum, cement, salt.
Minnesota	218,374,000	267,248,000	257,540,000	10	2.44	Iron ore, stone, sand and gravel, manganiferous ore.
Mississippi	67,644,000	119,317,000	103,984,000	24	.99	Petroleum, natural gas, natural-gas liquids, clays.
Missouri	103,928,000	108,291,000	111,287,000	22	1.05	Lead, cement, coal, stone.
Montana	87,735,000	103,841,000	97,756,000	25	.93	Petroleum, copper, zinc, coal.
Nebraska	6,704,000	8,385,000	10,102,000	41	.10	Cement, sand and gravel, stone, petroleum.
Nevada	40,923,000	42,479,000	37,376,000	32	.35	Copper, zinc, gold, lead.
New Hampshire	1,254,000	1,331,000	1,384,000	46	.01	Sand and gravel, stone, feldspar, beryllium concentrates.
New Jersey	38,433,000	44,388,000	38,584,000	30	.37	Zinc, stone, sand and gravel, iron ore.
New Mexico	157,548,000	220,075,000	199,629,000	13	1.89	Petroleum, potassium salts, copper, natural-gas liquids.
New York	122,333,000	143,623,000	138,265,000	20	1.31	Cement, iron ore, stone, petroleum.
North Carolina	16,386,000	18,231,000	19,755,000	38	.19	Stone, sand and gravel, talc and pyrophyllite, clays.
North Dakota	6,258,000	8,478,000	8,810,000	43	.08	Coal (lignite), sand and gravel, stone, clays.
Ohio	244,444,000	284,816,000	243,391,000	11	2.31	Coal, stone, cement, lime.
Oklahoma	354,387,000	506,846,000	483,696,000	6	4.58	Petroleum, natural-gas liquids, natural gas, coal.

Oregon	15,867,000	23,935,000	21,849,000	36	.21	Sand and gravel, stone, cement, gold.
Pennsylvania	1,248,817,000	1,386,960,000	1,034,837,000	3	9.81	Coal, cement, petroleum, stone.
Rhode Island	785,000	1,450,000	929,000	47	----	Stone, sand and gravel, graphite.
South Carolina	7,589,000	8,885,000	9,026,000	42	.08	Clays, stone, cement, vermiculite.
South Dakota	23,590,000	24,327,000	26,723,000	35	.25	Gold, stone, sand and gravel, clays.
Tennessee	79,941,000	93,599,000	77,348,000	26	.73	Coal, stone, cement, phosphate rock.
Texas	1,945,634,000	2,830,283,000	2,365,847,000	1	22.42	Petroleum, natural-gas liquids, natural gas, sulfur.
Utah	206,015,000	204,458,000	177,763,000	15	1.68	Copper, coal, lead, gold.
Vermont	14,717,000	15,999,000	17,384,000	39	.17	Stone, slate, asbestos, copper.
Virginia	130,296,000	143,333,000	116,410,000	21	1.10	Coal, stone, cement, sand and gravel.
Washington	38,051,000	48,928,000	40,863,000	29	.39	Cement, sand and gravel, coal, stone.
West Virginia	857,670,000	1,012,402,000	721,480,000	4	6.84	Coal, natural gas, petroleum, stone.
Wisconsin	34,491,000	37,108,000	35,878,000	33	.34	Stone, sand and gravel, iron ore, cement.
Wyoming	117,395,000	172,004,000	150,839,000	16	1.43	Petroleum, coal, natural gas, natural-gas liquids.
Total	9,609,717,000	12,273,317,000	10,554,234,000	----	100.00	Petroleum, coal, cement, iron ore.

TABLE 5.—Mineral production in the United State

ILLINOIS

Mineral	1947 Short tons (unless otherwise stated)
Cement ... barrels, 376 pounds net	7,155,280
Clays (including fuller's earth) [14]	2,086,674
Coal	67,860,011
Fluorspar	167,157
Lead ... Pb content	2,325
Lime (open-market)	299,187
Marl, calcareous (except for cement)	(2)
Natural gas ... thousand cubic feet	17,023,000
Natural-gas liquids:	
Natural gasoline ... gallons	47,180,000
LP-gases ... do	115,324,000
Petroleum (crude) ... barrels, 42 gallons	66,459,000
Sand and gravel	16,292,527
Sand and sandstone (ground)	198,500
Silver ... troy ounces, Ag content	1,790
Stone [15]	[16] 15,545,130
Tripoli	14,687
Zinc ... Zn content	10,073
Other minerals: Peat, stone (dimension sandstone, 1947: sandstone, 1948), and minerals indicated by footnote 2	
Total Illinois	
Clays sold or used for cement	148,306
Coke	3,805,374
Iron, pig	5,607,680
Sulfuric acid (from zinc smelting) ... 100-percent basis	173,275

INDIANA

Mineral	1947 Short tons (unless otherwise stated)
Clays (except for cement)	933,739
Coal	25,449,097
Marl, calcareous (except for cement)	27,412
Natural gas ... thousand cubic feet	877,000
Peat	3,957
Petroleum (crude) ... barrels, 42 gallons	6,095,000
Pyrites ... long tons	821
Sand and gravel	9,231,649
Stone [17]	[17] 5,589,550
Other minerals: Abrasive stones, cement, lime, and stone (dimension sandstone, 1947; sandstone, 1948–49)	
Total Indiana	
Clays sold or used for cement	248,139
Coke	8,785,687
Iron, pig	6,385,503

IOWA

Mineral	1947 Short tons (unless otherwise stated)
Cement ... barrels, 376 pounds net	6,155,670
Clays (except for cement)	648,680
Coal	1,684,055
Gypsum (crude)	656,982
Sand and gravel	6,473,087
Stone (except limestone for cement)	5,586,460
Other minerals	
Total Iowa	
Clays sold or used for cement	247,894

Employment and Injuries in the Mineral Industries[1]

By Forrest T. Moyer

GENERAL SUMMARY

EMPLOYMENT in the mineral industries declined 3 percent in 1949 to an average of 717,600 men working daily. Mineral plants were active an average of 207 days, 42 less than in 1948. Owing to the smaller labor force and to the smaller number of days of operation, the total man-hours worked in 1949 declined 20 percent from 1948. The average worker at mineral plants in 1949 had a shift of 7.88 hours, virtually unchanged from 1948. The average hours of work per man-year in the industries was 1,634, or 333 less than in 1948. The lower rate of operating activity in 1949 was noted in each of the major branches of the mineral industries. The greatest reduction in rate of operations was in the coal industry, in which extended work stoppages occurred during 1949. There was only a slight decrease in operating activity in nonmetal mines and quarries; in metal mines, coke ovens, and metallurgical plants the decline was moderate.

The injury record of the mineral industries was improved sharply in 1949. A total of 772 fatal injuries—455 less than in 1948—occurred at a frequency of 0.66 per million man-hours of exposure. This represented a 21-percent improvement over the corresponding rate in 1948 and was the best frequency rate for any year since complete injury data became available in 1930. An estimated total of 53,345 nonfatal injuries occurred in the extractive industries at a frequency rate of 45.50 per million man-hours during 1949. This was a reduction of 25 percent in number of injuries and 7 percent in the frequency of occurrence of nonfatal injuries from corresponding 1948 data. The rate of occurrence of nonfatal injuries in 1949 was lower than that of any year for which injury statistics are available.

There were no major disasters (a single accident in which five or more men are killed) in the mineral industries during 1949. This is the first calendar year in which there were no major disasters since complete fatality statistics on the mineral industries were first available in 1910. In 1948, there were 6 major disasters which caused fatal injuries to 49 men. All of the disasters in 1948 were in bituminous-coal mines.

[1] Data on petroleum, natural-gas, sand and gravel, and clay industries and on iron-smelting and stee industries are excluded from this chapter.

Salient statistics of employment and injury experience in the mineral industries in the United States, 1945–49, by industry groups

[1] [illegible]

[2] Average number of men at work each day mine was active. Because absenteeism and labor turn-over are taken into consideration, this number is lower than number of men available for work as measured by a count of names on payroll.

[3] Average in which operating time of each mine is weighted by average number of workers in mine.

[4] Totals of man-days and man-hours are additions of the rounded subtotals and may differ slightly from totals obtained before rounding.

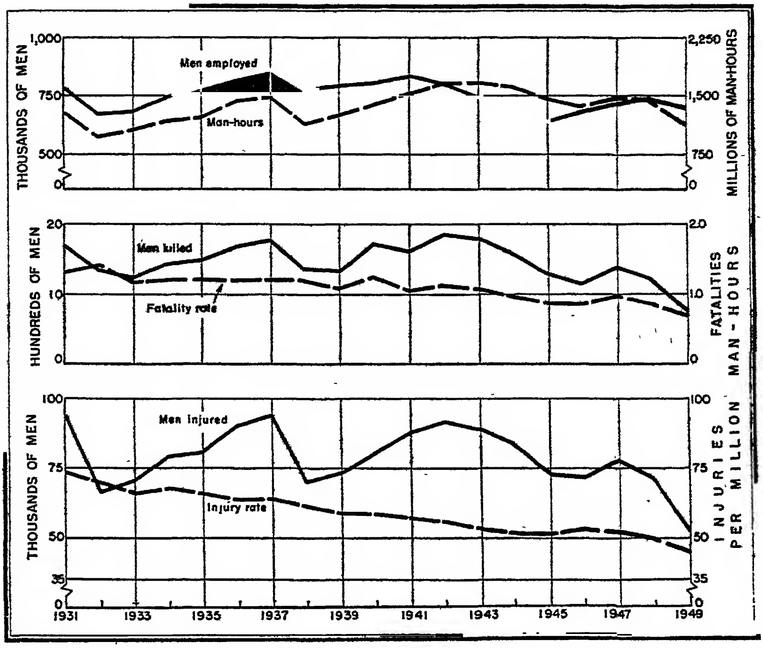

FIGURE 1.—Trends in employment and injury experience in the mineral industries of the United States, 1931–49.

Fatality experience was improved sharply in each of the major branches of the mineral industries except in metallurgical plants. Not only was there a sharp improvement in the rates, but also the number of fatal injuries was reduced appreciably. However, at metallurgical plants, the number of fatal injuries increased to 23 in 1949, and the fatality rate was 75 percent higher than in 1948.

The nonfatal injury record was better than in 1948 in all major branches in mineral industries. The sharpest improvement was at coke plants where the frequency rate of nonfatal injuries was 16 percent better than in 1948. The over-all improvement was achieved through a reduction in the number of nonfatal injuries which more than offset the shorter time of exposure to hazards in 1949.

Work Stoppages.—As in 1948, the mineral industries in 1949 were affected by work stoppages to a greater extent than any other segment of the national economy, because of the prolonged labor-management disputes in the coal industry. The total of 19,887,200 man-days of idleness from work stoppages in the mineral industries represented nearly 40 percent of the total man-days lost because of stoppages in all industries in the country, according to the United States Department of Labor. The total man-days of idleness in the mineral industries during 1949 was nearly double the corresponding figure for 1948.

There were 502 work stoppages in the mineral industries during 1949. Of these, 421 strikes causing a loss of 16,700,000 man-days were at bituminous-coal mines, 34 with a loss of 1,400,000 man-days were at anthracite mines, 17 with a loss of 166,000 man-days were in non-

metal mines and quarries, 9 with a loss of 970,000 man-days were at metal mines, and 9 with a loss of 544,000 man-days were at primary nonferrous smelters and refineries. The 3 stoppages at cement mills, 6 at petroleum refineries and 3 at coke plants had an aggregate loss of 107,000 man-days of work.

The coal industry was plagued with a number of work stoppages, beginning with a "memorial period" of 2-weeks duration that started on March 14 and closed bituminous-coal and anthracite mines east of the Mississippi River. This stoppage was called by the United Mine Workers as a period in memory of the miners killed or injured during 1948 and as a protest to the appointment made to the directorship of the Federal Bureau of Mines. The next major work stoppage affected the entire industry. It was called by the union on June 13 as a "brief stabilizing period of inaction." The men resumed work after 1 week. Following the coal miners' annual vacation (June 25 to July 4), the men in soft-coal mines east of the Mississippi River went on a "3-day workweek" under which the mines were operated Monday, Tuesday, and Wednesday of each week. In mines west of the Mississippi River and in anthracite mines in Pennsylvania, the men resumed the customary 5-day week following their vacation period. On September 19, the United Mine Workers struck all bituminous-coal and anthracite mines over a controversy on the health and welfare program of the union. After 2 weeks, on October 3, bituminous-coal mines west of the Mississippi River and anthracite mines in Pennsylvania were reopened for full production. Soft-coal mines east of the Mississippi River remained closed until November 10, when full production was resumed. Bituminous-coal mines east of the Mississippi were closed again on December 1 and 2, but work was resumed on December 5 with the announcement that the 3-day workweek was again to be effective in all soft- and hard-coal mines. In announcing the short workweek for December, the union stated that mines that signed contracts with them could operate the full week. At the end of December, the union announced that mines with an aggregate annual production of 10 million tons of coal had signed wage agreements that raised payments to the health and welfare fund program from 20 to 35 cents per ton and provided for an increase of 95 cents in daily wages.

Average Earnings.—Average hourly earnings increased in each of the mineral industries for which data are published by the Bureau of Labor Statistics, as shown in the accompanying table. However, due to the lessened number of active days in 1949, the average weekly earnings fell appreciably in anthracite and bituminous-coal mining. There also was a slight decrease in average weekly earnings at copper mines. In all other mineral industries, the average weekly earnings in 1949 were higher than in 1948.

Labor Turn-Over.—Labor turn-over in the mineral industries for which data are published by the Bureau of Labor Statistics was highest in metal mining and lowest in petroleum refining. It is notable

that separation rates of labor turn-over were higher than the accession rates in 1949 in each of the mineral industries, whereas in 1948 the accession rates were higher than the separation rates in each industry except anthracite mining.

Work stoppages, average earnings, and labor turn-over in certain mineral industries in the United States, 1947–49

[Bureau of Labor Statistics]

Industry and year	Work stoppages [1]		Average earnings [2]		Labor turn-over rates [3]	
	Number	Man-days lost (thousands)	Weekly	Hourly	Accession	Separation

NATIONAL SAFETY COMPETITION

Mineral operations competing in the twenty-fifth annual National Safety Competition, conducted by the Bureau of Mines, compiled an outstanding safety record during 1949. The over-all injury experience at the record total of 646 enrolled mineral plants was a severity rate of 5.56 days of disability per 1,000 man-hours of work and a frequency rate of 33.21 per million man-hours. The injury-severity rate was lower by a substantial margin than in any other year in the history of the competition. The injury-frequency rate was the second lowest in the 25 years of the competition and was only slightly above the record low rate achieved in 1940. Of the enrolled mines and quarries, 202 operations had no disabling injuries during 1949. The aggregate worktime at these injury-free plants was nearly 16 million man-hours. Trophy awards for the best safety records in each of the six groups of the 1949 competition were made to the following:

Anthracite Underground Mines.—Stevens Shaft mine, Kehoe-Berge Coal Co., Exeter, Pa.

Bituminous-Coal Underground Mines.—Reliance No. 7 mine, Union Pacific Coal Co., Reliance, Wyo.

Metal Underground Mines.—No. 2 mine, American Zinc Co. of Tennessee, Mascot, Tenn.

Nonmetal Underground Mines.—Bellefonte mine, National Gypsum Co., Bellefonte, Pa.

Open-Pit Mines.—Embarrass mine, Pickands Mather & Co. (Lake Mining Co.), Biwabik, Minn.

Quarries.—Dolonah quarry, Tennessee Coal, Iron & Railroad Co., Bessemer, Ala.

COAL MINES

The safety record of coal mines in the United States during 1949 was improved over 1948 and was better than in any year since 1930, when complete injury statistics were first compiled. The tentative frequency rate—59.01 injuries (fatal and nonfatal) per million man-hours—was a decrease of 3 percent from 1948. The previous record low rate for the coal industry was 60.26 injuries per million man-hours in 1944. Both the bituminous-coal and anthracite industries contributed to the record in 1949, and the frequency per million man-hours of both fatal and nonfatal injuries in each industry fell to record low rates.

Based upon the estimated output of 477,700,000 tons of anthracite and bituminous coal, the fatal rate per million tons was improved to 1.24 in 1949, the lowest annual rate in a statistical history extending back to 1910. The nonfatal injury rate per million tons, likewise, was improved appreciably to 79.06 in 1949.

The 593 fatal injuries in 1949 were 406 fewer in number than in 1948 and represented the lowest annual total since complete fatality statistics were first compiled. No major disasters (a single accident in which five or more men are killed) occurred in 1949 in either bituminous-coal or anthracite mines. This is the first calendar year the entire coal industry has operated without a major disaster since complete fatality records became available in 1910. The number of nonfatal injuries during 1949 is estimated to be 37,765, or 29 percent less than in 1948.

The average number of men working daily in coal mines declined 5 percent to a total of 482,800 men in 1949. Due to extended work stoppages and a 3-day workweek during part of 1949, the mines were active an average of 173 days, a reduction of 54 days from 1948. As a result, the aggregate hours of work in coal mines declined 28 percent from 1948. The average miner during 1949 worked a 7.77-hour shift and accumulated a total of 1,346 hours of work, 424 hours less than in 1948.

Bituminous-Coal Mines.—The safety record of the bituminous-coal industry during 1949 was better than in any year since 1930, when complete injury data were first available. The tentative rate of 55.58 injuries (fatal and nonfatal) per million man-hours was 3 percent below the rate of 57.43 in 1948 and also was lower than the previous low record of 57.25 injuries per million man-hours in 1944. The estimate of 500 fatalities in bituminous-coal mines was 362 fewer than in 1948 and was lower than in any other year in the statistical history of the industry. The fatality rate of 0.92 was the best on record, and for the first time since such rates were compiled in 1930 it was less than one per million man-hours of exposure. The 1949 fatality rate represented a 20-percent improvement over 1948. The more favorable fatality experience in bituminous-coal mines also is shown by the rate of 1.15 fatal injuries per million tons, which set a new low annual record for the industry. It is notable that 1949 was the first calendar year in which the industry

was free of a major disaster. In 1948 there were 6 major disasters which resulted in the death of 49 men in soft-coal mines. The estimated total of 29,585 nonfatal injuries was 30 percent lower than in 1948. The frequency rate for these nonfatal injuries was 3 percent better than in 1948 and was lower than in any year since 1930 when the data were first compiled. The frequency of occurrence of nonfatal injuries per million tons of coal mined also was improved in 1949 to a rate of 68.01.

Employment and injury experience at coal mines in the United States, 1945–49

[1] Includes lignite.

Of total fatalities at bituminous-coal mines, 441 occurred in underground workings, 43 at surface works associated with deep mines, and 16 at stripping operations. The total of 441 killed in underground workings was 42 percent lower than the 761 in 1948. All major causes of underground fatal injuries showed a lower number of deaths during 1949 than in 1948. The hazard of falls of roof and face was controlled more effectively in 1949, and the total of 283 fatalities from this cause was 192 less than in 1948. Underground haulage accidents killed 104 men in 1949, likewise a marked reduction from 1948. Fatal injuries in gas and dust explosions were reduced to an all-time low of three in 1949; the three fatalities resulted from one local explosion.

Employment at bituminous-coal mines declined 6 percent to an average of 404,800 men working daily during 1949. Due to strikes and 3-day workweeks, the mines were active an average of only 169 days or 51 less than in 1948. Total man-hours worked in soft-coal mines fell 28 percent from 1948. The average worker had a 7.89-hour shift, and the average work year per man was 1,337 hours, a reduction of 404 hours from 1948.

Anthracite Mines.—Injury experience in Pennsylvania anthracite mines was improved over 1948 and was better than in any year since

complete injury data were first available in 1930. The tentative frequency rate (fatal and nonfatal) was 76.03 per million man-hours. An estimated total of 93 fatalities occurred in anthracite mines in 1949, a reduction of 44 from 1948. For the second successive year there was no major disaster in the anthracite mines. The fatality rate per million man-hours was reduced 7 percent from 0.92 in 1948 to 0.85 in 1949. This was the best frequency rate of fatal injuries in the accident-statistical history of the industry and marked the second consecutive year in which this rate was lower than one fatal injury per million man-hours. Based upon an estimated production of 42,700,000 tons of clean coal, the frequency of 2.18 fatal injuries per million tons in 1949 also was the lowest on record for the industry. A total of 8,180 nonfatal injuries occurred at rates of 75.18 per million man-hours of exposure and 191.57 per million tons of coal produced—both improvements over corresponding data for 1948.

At anthracite operations, 85 fatal injuries occurred in underground workings, 7 at surface works associated with deep mines, and 1 in stripping operations. There was a marked reduction in the number of fatal injuries from falls of roof and face, which killed 55 men in 1949. The number of fatal injuries in underground workings was reduced also for explosives, electricity, machinery, and miscellaneous causes. However, fatalities from haulage accidents, explosions, and shaft accidents were higher in 1949 than in 1948. Three local explosions in 1949 killed five men, whereas two men were killed in a local explosion in 1948. At strip operations, the reduction in fatal injuries from nine in 1948 to one in 1949 is a notable safety achievement.

The average number of men working daily in anthracite mines during 1949 was virtually unchanged from 1948. Due principally to work stoppages and the 3-day workweek, the mines were active an average of 193 days, or 70 less than in 1948. Aggregate worktime in the industry declined 28 percent to a total of 108,800,000 hours in 1949. The average shift was 7.22 hours in 1949, and the average employee worked a total of 1,395 hours, 536 less than in 1948.

METAL MINES

The over-all injury record at metal mines during 1949 improved. A total of 74 fatal injuries, or 30 less than in 1948, occurred at a rate of 0.51 per million man-hours, a reduction of 20 percent. Fatal experience was better in each group of mines except at lead-zinc mines, where the fatality frequency rate increased sharply over 1948. For the third successive year, the nonfatal-injury frequency rate at metal mines was reduced; the rate for 1949 was 46.18 per million man-hours. The improvement in 1949 resulted from more favorable frequency rates in iron, copper, and lead-zinc mines, which more than offset the less favorable rates in the other metal-mine groups.

Employment decreased slightly to an average of 70,300 men working daily. Employment was lower during 1949 for each group of metal mines except iron mines, where there was a slight increase. The aggregate time worked at metal mines declined 11 percent from 1948 to a total of 143,770,000 man-hours. This decline resulted largely from the smaller number of active mine days, which in 1949 averaged 255, or 27 less than in 1948. Work stoppages caused part of this reduction

in active days, particularly at iron mines, which were closed during the "steel" strike through October and the early part of November. The average length of shift for all metal mines was 8.01 hours, and the average employee worked 2,045 hours during 1949, a reduction of 216 hours from 1948.

Employment and injury experience at metal mines in the United States, 1945–49, by industry groups

[1] Includes antimony, bauxite, chromite, cobalt, manganese, mercury, molybdenum, pyrite, titanium, tungsten, and vanadium-uranium mines.

Iron Mines.—Injury experience at iron mines was appreciably better than in 1948. The frequency rate for the 22 fatal injuries in 1949 was 0.40, or 26 percent below 1948. The frequency rate for nonfatal injuries was improved by 9 percent to a rate of 20.87 per million man-hours in 1949. Employment increased slightly; but, as the mines were active 40 fewer days in 1949, the total worktime declined 13 percent from 1948. The "steel" strike that lasted from October 1 until the first half of November virtually closed the iron-ore-mining industry during this period. The average employee at iron mines worked

a 8.02-hour work shift and accumulated a total of 1,977 hours of work during 1949 compared with 2,304 hours in 1948.

Copper Mines.—The safety record at copper mines improved sharply during 1949. The fatality frequency rate of 0.35 was less than half that of the preceding year and resulted from the 61-percent drop in the number of fatal injuries. The number of nonfatal injuries was reduced 28 percent from 1948, and the resulting frequency rate of 32.76 per million man-hours represented a 17-percent improvement. The average number of men working daily declined to 15,800 in 1949. These men worked 32 days less than in 1948 and had an aggregate worktime of 34,490,000 man-hours, 13 percent below 1948. The work stoppage at a large open pit, which had started in the latter part of 1948, ended during the first half of February 1949. The average length of shift of 8.00 hours was unchanged from 1948; but, due to the smaller number of active mine days, the average employee worked 2,183 hours in 1949, or 255 less than in 1948.

Lead-Zinc Mines.—Fatality experience at lead-zinc mines was worse than in 1948. There were 28 fatal injuries in 1949, and the frequency rate increased 35 percent to 0.88 per million man-hours. As the decline in number of nonfatal injuries was greater proportionally than the decrease in man-hours of exposure, the nonfatal-injury frequency rate improved by 2 percent in 1949. The slight decline in employment, together with the smaller number of days active, caused a 6-percent decline in total man-hours worked. The average employee had a 7.99-hour work shift and a total of 2,009 hours of work during the year, or 103 hours less than in 1948.

Gold-Silver Lode Mines.—The fatality record was improved at gold-silver lode mines, but the nonfatal-injury record was not as good as in 1948. The total of 10 fatals was 3 less than in 1948. They occurred at a frequency of 0.96 per million man-hours, a 17-percent improvement. There was only a slight reduction in the number of nonfatal injuries; and, as the total worktime was reduced in greater proportion, the nonfatal-injury frequency rate increased 7 percent to 92.79 per million man-hours in 1949. The average number of men working declined 9 percent from 1948. Although these men worked 7 more days in 1949, the aggregate worktime declined 8 percent from 1948. The average shift in 1949 was 7.74 hours, a reduction from the 7.85-hour shift in 1948. The average employee worked 2,167 hours during 1949, or 20 more than in 1948.

Gold Placer Mines.—There were no fatal injuries at gold placers during 1949, whereas one occurred in 1948. The total of 190 nonfatal injuries was 10 more than in 1948, and the frequency of occurrence of these increased 17 percent to a rate of 28.49 in 1949. Because both employment and the average number of days active were lower than in 1948, the total man-hours of work declined 10 percent in 1949. The average employee worked 8.61 hours per day and accumulated a total of 1,906 hours during 1949.

Miscellaneous Metal Mines.—Fatality experience at miscellaneous metal mines improved. The two fatal injuries occurred at a rate of 0.34 per million man-hours in 1949, a 26-percent betterment over 1948. There was a slight increase in the number of nonfatal injuries; and this increase, together with the reduced man-hours of exposure,

resulted in a nonfatal-injury frequency rate 17 percent higher than in 1948. Employment declined slightly from 1948; and, because these mines were active 19 less days, the aggregate worktime during 1949 was 11 percent below 1948. There was a slight reduction in the average length of shift to 7.99 hours in 1949. The average worker accumulated 2,100 hours during 1949, or 185 less than in 1948.

NONMETAL MINES (EXCEPT STONE QUARRIES)

Employment gained slightly in 1949 to a total of 12,300 men at work daily in this group of nonmetal mines, which comprises barite, feldspar, fluorspar, gypsum, magnesite, mica, phosphate rock, rock salt, sulfur, and miscellaneous nonmetallic-mineral operations. However, as the operations were active an average of 276 days or 11 less than in 1948, the total hours of worktime during 1949 were slightly less than in the preceding year. The injury record in nonmetal mines improved in 1949. The total of 10 fatal injuries was lower than in any year since 1939. They occurred at a rate of 0.37 per million man-hours. The degree of improvement in the nonfatal-injury record was not as sharp as with fatalities. The nonfatal injuries occurred at a rate of 41.64 per million man-hours, which was lower than in any other year since 1939.

Employment and injury experience at nonmetal mines (except stone quarries) in the United States, 1945–49 [1]

Year	Men working daily	Average active mine-days	Man-days worked	Man-hours worked	Number of injuries		Injury rates per million man-hours	
					Fatal	Nonfatal	Fatal	Nonfatal
1945	10,371	291	3,015,980	24,612,921	16	1,145	0.65	46.52
1946	11,312	291	3,296,626	26,876,871	26	1,369	.97	50.94
1947	12,176	292	3,554,901	28,809,150	12	1,308	.42	45.40
1948	11,950	287	3,432,304	27,784,119	15	1,176	.54	42.33
1949 (preliminary)	12,300	276	3,392,000	27,380,000	10	1,140	.37	41.64

[1] Includes barite, feldspar, fluorspar, gypsum, magnesite, mica, phosphate rock, rock salt, sulfur, and miscellaneous nonmetallic-mineral mines.

STONE QUARRIES

Injury experience in the quarrying industries was appreciably better in 1949 than in 1948. The 65 fatal injuries during the year occurred at a rate of 0.37 per million man-hours, a decrease of 12 percent from 1948. The number of nonfatal injuries declined 404 to a total of 4,590 during 1949. The nonfatal-injury frequency rate of 25.96 was 7 percent lower than in 1948.

The average number of men working daily during 1949 advanced 3 percent to a total of 79,900. Due to 10 fewer working days, these men worked an aggregate of 176,800,000 man-hours or slightly less than in 1948. The average length of shift fell slightly to 8.07 hours in 1949. As a result of the reductions in active plant-days and length of shift, the average employee in the quarry industry worked 2,213 hours in 1949 compared with 2,316 hours in 1948.

Cement Quarries.—The cement industry had the sharpest improvement in injury experience among the quarry industries. The rate for

the 18 fatal injuries in 1949 was 0.24 per million man-hours or 27 percent below 1948. Likewise, the nonfatal-injury frequency rate was reduced 21 percent from 1948 to 8.46. This was the best annual frequency rate for nonfatal injuries in the cement industry since these rates were first compiled in 1931. Employment increased slightly to a total of 29,100 men working at cement plants. However, because there was 1 less day active, a slight reduction in the average length of shift worked, the aggregate worktime in 1949 was only 1 percent larger than in 1948. The average worker in 1949 had a shift of 7.83 hours.

Employment and injury experience at stone quarries in the United States, 1945–49, by industries

[1] Includes burning or calcining and other mill operations.

Limestone Quarries.—The safety record of limestone operations was slightly better in 1949 than in 1948 as a result of the improvement in nonfatal-injury experience. There were 25 fatalities, 1 less than in 1948. However, the fatality rate was unchanged from 1948, due to the shorter time of exposure to hazard in 1949. The fatality frequency rate has improved in only a slight degree in recent years. On the other hand, the frequency rate of nonfatal injuries has been lowered each year since 1946. Employment gained 7 percent in 1949, but because of an average of 23 fewer days of activity, the total man-hours of work was 3 percent below 1948. The average employee worked 1,857 hours during 1949, a decrease of 188 from 1948, because of the reduced number of active days. The average shift of 8.40 hours in 1949 was virtually the same as in 1948.

Lime Plants.—The nonfatal-injury frequency rate at lime plants in 1949 was improved 9 percent over 1948. However, the total of 10 fatals represented a frequency of 0.45 per million man-hours, which was less favorable than in 1948. The nonfatal-injury record at lime plants has improved appreciably each year since 1946, whereas the fatal record, as indicated by frequency rates, has become worse each year since 1946. A 2-percent decline in the average number of men working daily, together with two fewer days of work and a slightly shorter length of shift caused a 3-percent decline in the total man-hours worked in the industry during 1949. The average shift in 1949 was 7.85 hours.

Marble Quarries.—No fatal injuries were reported at marble quarries during 1949. The frequency of nonfatal injuries, however, increased 14 percent to 32.31 per million man-hours. Activity, as gaged by employment data, was at a higher level in 1949 than in 1948. The average number of men at work daily gained 20 percent over 1948, and the total man-hours of worktime showed a nearly similar gain of 16 percent. The average employee had a 7.96-hour shift and worked 2,064 hours during the year.

Granite Quarries.—Injury experience at granite operations improved considerably in 1949. There were three fatalities compared with six in 1948. The fatality frequency rate was less than half that of 1948; and for nonfatal injuries, the rate was 11 percent better. Employment increased 3 percent and the total worktime 2 percent in 1949. The average length of shift was increased to 8.51 hours in 1949, but the average worktime per employee for the year decreased slightly to a total of 2,128 hours because of an average of six fewer working days.

Traprock Quarries.—The frequency record of nonfatal injuries at traprock operations was improved 5 percent over 1948, and the rate was reduced to 48.12. Although there were four fatal injuries in each year, the frequency of fatalities in 1949 increased to 0.84 because the time of exposure was lower. The number of men worked daily was virtually unchanged from 1948 but as there were 15 fewer working days in 1949, the total man-hours declined 6 percent. The average employee worked 1,912 hours during 1949 and had a shift of 8.58 hours.

Slate Quarries.—Injury experience at slate operations was less favorable in 1949. The fatality frequency rate of 3 fatal injuries was 15 percent higher than in 1948, and the rate of occurrence of nonfatal injuries increased 21 percent. The increased frequency rates resulted largely from the reduced worktime in 1949. The average number of men working declined 8 percent to a total of 1,800 in 1949. These men worked 12 percent fewer man-hours and had an average daily shift of 8.56 hours. The average worktime per man-year was 2,206 hours, or 105 less than in 1948.

Sandstone Quarries.—The safety record at sandstone operations was less favorable than in 1948, and the frequency rates of both fatal and nonfatal injuries increased. There were 2 fatal injuries in each year, and nonfatal injuries dropped to 335 in 1949. The less favorable rates of occurrence resulted from a 13-percent decline in the aggregate worktime in the industry. Employment declined 4 percent, and there were 23 fewer days of work in 1949. The average worker had a shift of 8.27 hours and worked 1,890 hours during the year—199 less than 1948.

COKE PLANTS

The injury record at coke plants improved sharply in 1949. The fatality rate of 0.11 per million man-hours was the best in a statistical history, which started in 1916. The nonfatal-injury frequency rate of 11.04 was 16 percent better than in 1948 and was lower than in any other year since 1940. A total of 7 fatal and 690 nonfatal injuries occurred in 1949. Employment declined slightly to a total of 24,600 men, and the total man-hours worked during 1949 was 11 percent below 1948. Due to the effects of the strikes in the steel and coal-mining industries during 1949, coke plants were active an average of 320 days or 30 less than in 1948.

Byproduct Coke Plants.—The fatality frequency rate of 0.12 at byproduct-coke plants in 1949 was better than in any other year in the history of injury statistics on the industry. The frequency rate of nonfatal injuries was 9 percent lower than in 1948 and was the lowest annual rate since 1942. There were 7 fatal and 570 nonfatal injuries in 1949. The average number of men working daily declined slightly; however, the total man-hours worked at these plants during 1949 decreased 8 percent below 1948 because of the 16 fewer days of work in 1949. Byproduct coke plants were not affected materially by the strikes in the coal-mining industry, as coal stocks were maintained as high as possible through the year. However, the work stoppage in the steel industry in the latter half of the year caused the furnace plants to bank ovens. The average work shift in 1949 was 7.98 hours, virtually the same as in 1948.

Employment and injury experience at coke plants in the United States, 1945–49

Type and year	Men working daily	Average active plant-days	Man-days worked	Man-hours worked	Number of injuries		Injury rates per million man-hours

Beehive-Coke Plants.—There were no fatal injuries at beehive-coke plants during 1949, whereas, in 1948 3 men were killed. The nonfatal-injury frequency of 33.80 per million man-hours was a 13-percent improvement over 1948 and was better than in any other year since 1938. Employment was slightly higher in 1949; but, as a result of the steel and coal strikes and of the 3-day week at coal mines, the beehive plants were active an average of only 140 days during the year, or 114 days less than in 1948. The aggregate worktime declined 43 percent in 1949. The average employee worked a 7.44-hour shift and had a total of 1,044 hours of work during the year or 856 less than in 1948.

METALLURGICAL PLANTS

The over-all fatality record at metallurgical plants was worse than in 1948 because of the sharp rise in fatality experience at nonferrous smelters, which more than offset an improvement at metal mills. The nonfatal-injury frequency of 22.49 was only slightly lower than in 1948. This slight improvement resulted from more favorable experience at metal mills which more than compensated for the slightly less favorable record at nonferrous smelters. There were 23 fatalities and 2,520 nonfatal injuries in 1949. Over-all employment at metallurgical plants changed only slightly from 1948. However, the aggregate man-hours of work in 1949 were 7 percent lower than in 1948 because the plants were active 23 fewer days.

Ore-Dressing Plants.—This group includes crushing, screening, washing, jigging, magnetic separation, flotation, and other milling operations on metallic ores. Injury experience at metal mills was better in 1949. There were 7 fatalities and the fatal frequency rate was reduced to 0.20 per million man-hours. The nonfatal injuries totaled 770, and the frequency of such injuries was reduced to 21.82. Fatal experience was better in each group of mills except iron mills, in which three men were killed in 1949 compared with none in 1948. The non-

fatal-injury experience was improved at each group except lead-zinc mills, in which there was virtually no change in rate of occurrence, and in miscellaneous metal mills, where the frequency rate increased sharply to 52.48 per million man-hours. The average number of men working daily increased for each group except gold-silver mills. The over-all gain was 6 percent. Although employment was slightly lower at gold-silver mills, the plants were active 16 more days in 1949, with the result that man-hours worked in this group were slightly higher than in 1948. At miscellaneous metal mills, the gain in employment resulted in an appreciable increase in man-hours worked in 1949. In the other groups of metal mills, the plants were active fewer days in 1949 than in 1948, and the man-hours of work declined slightly in each group in 1949. The average shift (8.01 hours) was unchanged from 1948.

Employment and injury experience at ore-dressing (metallic) plants in the United States, 1945–49, by industries [1]

[1] Includes crushers, grinders, washers, ore concentrators, and sintering, cyaniding, leaching, and other ore-dressing plants and auxiliary works.
[2] Includes aluminum, antimony, chromium, manganese, mercury, molybdenum, tungsten, vanadium, and other metals.

Nonferrous Reduction Plants and Refineries.—The reduction plants and refineries in this classification are engaged in the primary extraction of nonferrous metals from ores and concentrates and the refining of crude primary nonferrous metals. Iron and steel plants are excluded.

Injury experience at nonferrous smelters and refineries was less favorable in 1949. The total of 16 fatalities occurred at a rate of 0.21 per million man-hours compared with 5 fatal injuries and a rate of 0.06 in 1948. The fatality frequency rate was worse at each group of smelters except at miscellaneous metal smelters, at which the rate was unchanged from 1948. Nonfatal-injury experience was slightly better at copper and lead smelters, but these improvements were more than offset by less favorable frequencies at zinc and miscellaneous-metal smelters. Employment declined slightly at each group of smelters except at lead smelters. Man-hours worked declined in each group and the over-all decrease in worktime for smelters was 10 percent from 1948. Plants in each group of smelters were active fewer days in 1949; for all smelters, the average plant was active 309 days—21 less than in 1948.

Employment and injury experience at primary nonferrous reduction and refinery plants in the United States, 1945–49, by industries [1]

[2] Includes antimony, magnesium, mercury, and tin plants.

PART II. COMMODITY REVIEWS

Abrasive Materials

By Robert W. Metcalf

GENERAL SUMMARY

BOTH increased and decreased output was recorded in the abrasive industry in 1949. Output of pumice and pumicite rose to a new record, and diatomite increased slightly over the high level of 1948. Sales of tripoli and emery were somewhat less than in 1948, and sales of quartz, grindstones, and garnet decreased substantially. Production of silicon carbide in 1949 increased 7 percent to the highest figure since the record year 1943. Production of aluminum oxide and shipments of metallic abrasives in 1949 were 19 and 29 percent, respectively, below the previous year.

The total value of imports of natural and artificial abrasive materials in 1949 declined 42 percent from that in 1948. Imports of diamond bort, carbonados and ballas, and diamond dust dropped sharply, as did corundum ore. On the other hand, receipts of emery ore and crude pumice were larger than in 1948. Silicon carbide and

Salient statistics of the abrasives industries in the United States, 1948–49

	1948		1949		Percent of change in 1949	
	Short tons	Value	Short tons	Value	Short tons	Value
Natural abrasives (domestic) sold or used by producers:

Foreign trade (natural and artificial abrasives):						
Imports		[4] 45,165,069		26,336,325		−42
Exports		[4] 15,267,670		17,447,399		+14

[1] Average annual figure for 1945–47 was 213,588 short tons valued at $4,307,988; Bureau of Mines not at liberty to publish annual data separately.
[2] Tonnage not recorded.
[3] Includes Canadian production.
[4] Revised to include data for artificial abrasives.

aluminum oxide imports were about one-quarter less in 1949. Imports of iron and steel grit, shot, and sand are small in actual volume but showed a very high proportional increase.

This chapter includes data for most of the materials used for abrasive purposes, but certain clays, carbides, oxides, and other substances noted later under Miscellaneous Mineral Abrasive Materials are not included in the statistics shown herein. Certain of the abrasive products for which figures are given also have important nonabrasive uses.

Natural and artificial abrasives were compared[1] in the literature; and developments in the abrasive industries were presented, particularly the processing of garnet and the preparation of the hard carbides.[2] Mechanical polishing methods and agents were reviewed,[3] and precision tumbling procedures outlined.[4]

NATURAL SILICA ABRASIVES

Diatomite.—The high levels achieved in the production of diatomite in recent years were continued in 1949. Output data for that year, however, may not be published by the Bureau of Mines, as they would reveal statistics of individual companies. Annual production for the 3-year period 1945–47 averaged 213,588 short tons valued at $4,307,088, compared with 174,957 tons valued at $3,298,178 for 1942–44 and 120,167 tons valued at $1,915,405 for 1939–41.

Diatomite was produced for sale in 1949 in four States—California, Oregon, Nevada, and Washington. The largest producer was California. Increases were reported in three of the four States reporting production. Major uses for which diatomite was consumed, with the approximate portion indicated for each use, follow: Filtration, about three-fifths of the total; fillers, about one-quarter; insulation, about one-tenth; and other uses, including abrasives, the remainder.

Recent developments in the industry included discontinuance of the operations of the General Diatomite Co., Fallon, Nev., and abandonment of its Kittitas, Wash., plant by the Great Lakes Carbon Corp., Dicalite Division, Los Angeles, Calif. The latter firm was reported to have purchased during 1949 the former Diatoms, Inc., operation near Bradley, Calif. The Quincy Corp., 901 Chrysler Building, New York, N. Y., acquired the assets and business of the Dia-Cousti-Lite Products Co., Quincy, Wash. A description of the Dia-Cousti-Lite operations was published.[5] As of January 1, 1950, the Corliss-Kaiser Co., Inc., Yakima, Wash., was reorganized and the name of the firm changed to Kaiser Mining & Manufacturing Co., Inc., with offices at 205 Mercy Building, Yakima, Wash. Recovery and milling operations at the Johns-Manville Products Corp. plant at Lompoc, Calif., were described.[6]

[6] Huttl, J. B., Diatomite, Its Mining and Processing: Eng. and Min. Jour., vol. 150, No. 8, August 1949, pp. 75–77 (flow sheet).

As quoted in E&MJ Metal and Mineral Markets, price quotations of diatomite during 1949 continued unchanged from previous years as follows (per ton, crude, in bulk, dried, nominal): Nevada—98- to 100-mesh, $25; low-temperature insulation, $25; high-temperature insulation, $40; fine abrasive, 2 to 3 cents per pound (bags are extra); California filtration grades, $20 to $50 per ton f. o. b. mill.

The use of diatomaceous earth in making a lightweight aggregate for concrete was described, and its advantages were set forth.[7] Treating finely ground diatomite with air-entraining agents resulted in much improved workability and less bleeding and segregation, as well as lower water requirements and less drying shrinkage than for ordinary concrete.[8] It was claimed that resistance to freezing and thawing also was greatly increased.

Filtration of sulfur through diatomaceous earth to remove fly ash and other airborne dusts picked up during transportation and storage proved successful, according to the trade press.[9] An automatic, self-renewing filtering system using diatomite as a filter aid was said to be satisfactory for all types of difficult electroplating solutions, including those from cyanide plating tanks and those composed of iron and aluminum hydrides.[10] Diatomite filters for swimming pools were described.[11] A brief account of the use of diatomite as in inert filler in both natural and synthetic rubber was given in an article on inorganic mineral substances used in the rubber industry.[12]

French occurrences of diatomites were described.[13] Recoverable reserves of diatomite on the Scottish Isle of Skye have been estimated at from 250,000 to 300,000 tons,[14] and a limited production was obtained during 1949.[15] Descriptions of Japanese diatomite deposits and discussion of possible industrial applications were published in a series of papers.[16] Swedish use of diatomaceous earth in making porous insulating brick was noted.[17] Treatment of English cider with a diatomaceous filter aid improved the quality of the product, it was claimed.[18]

Tripoli.—Sales of tripoli, amorphous silica, and rottenstone in 1949 totaled 25,525 short tons, valued at $690,564, a decrease of 5 percent in tonnage and 2 percent in value compared with 1948, although considerably above the levels of the war years 1942 to 1945. States in which these materials were produced in 1949 were Illinois, Missouri, and Pennsylvania.

The chief use of tripoli in 1949 was as an abrasive in polishing and buffing compositions. Partly estimated data indicated a decline for this purpose and a small increase in the market for fillers. Miscellaneous uses, including foundry facing and rotary drilling mud, decreased somewhat in 1949.

Tripoli[1] sold or used by producers in the United States, 1943–46 and 1947–49, by uses

Year and use	Short tons	Value	Year and use	Short tons	Value
1943	14,912	$244,365	1948: Abrasives	22,193	$606,402
1944	18,425	301,863	Filler	2,723	45,000
1945	18,247	306,829	Foundry facing, etc.	1,929	54,121
1946	28,955	549,099	Total	26,845	705,523
1947: Abrasives	29,866	654,232	1949: Abrasives	20,972	587,241
Filler	2,573	47,640	Filler	2,820	53,938
Foundry facing, etc.	2,139	49,550	Foundry facing, etc.	1,733	49,385
Total	34,578	751,422	Total	25,525	690,564

[1] Including Pennsylvania rottenstone.

Quotations on tripoli in E&MJ Metal and Mineral Markets remained throughout 1949 at the same levels as in recent preceding years (per short ton, f. o. b. Missouri, in paperlined burlap bags, minimum carlots 30 tons): Once-ground, through 40-mesh, rose or cream, $14.50; double-ground, through 110-mesh, rose or cream, $16; and air-floated, through 200-mesh, $26. Quotations appearing in Oil, Paint and Drug Reporter for dry-ground, 325-mesh amorphous silica, f. o. b. works, Illinois, remained at $20 to $30 per ton during 1949 for carlot shipments. Less-than-carlot shipments, which at the beginning of 1949 were quoted at $25 per ton, were changed to $25–$40 after April 1. The same journal quoted prices on rottenstone in 1949 as follows: $36 per short ton, at mines, in bags, for carlots, and $43 for less than carlots.

Companies producing tripoli, amorphous silica, and rottenstone in 1949 were: Illinois (amorphous silica)—Ozark Minerals Co., Cairo; Oklahoma (mines) and Missouri (mill)—American Tripoli Corp., Seneca, Mo.; and Pennsylvania (rottenstone)—Penn Paint & Filler Co., Antes Fort, and Keystone Filler & Manufacturing Co., Muncy. Two new firms have been organized to mine and process amorphous silica near Rogers, Ark.—Corona Silica Corp., 2240 Commerce Building, Houston 2, Tex., and Oak Ridge Minerals, Inc., Rogers, Ark. Milling equipment was being installed in 1949, but neither company was in production.

A description of Russian experiments in producing tripoli brick was published.[19] The use of tripoli and other materials as coating agents in mould washes, parting powders, and other refractory mixtures in the foundry was detailed.[20] Possible competitors of tripoli are buffing and polishing compounds said to be made from conglomerate sands.[21]

Polishing of gems (particularly sapphire) with tripoli and other polishing agents was described.[22] Although many lapidaries still prefer tripoli, it is said that the recently introduced micro-size grit diamond powder and synthetic sapphire polishing powder are replacing tripoli in the polishing of sapphire.

Quartz.—Sales of crude, crushed, and ground quartz from pegmatite veins or dikes and from quartzite in 1949 dropped 34 percent in tonnage and 37 percent in value compared with 1948, but the tonnage remained somewhat higher than in 1947. The total value for 1949 was topped only by that of 1948. Principal uses for which the re-

Quartz (crude, crushed, and ground) [1] sold or used by producers in the United States, 1945–49

Year	Crude		Crushed		Ground		Total

ported tonnage was consumed included the manufacture of ferrosilicon and glass, with smaller quantities for abrasives and as an ingredient in pottery, porcelain, or tile.

Tonnages reported as crude and crushed quartz in 1949 declined sharply, and ground material increased 19 percent in quantity and 14 percent in value compared with 1948. These statistics do not include sales of quartzite to cement mills and certain sales of quartz or quartzite for use in the manufacture of ferrosilicon. Production in each of the States or groups of States given in the accompanying table, except Connecticut, showed large decreases.

The average value of the total quartz reported in this section was $4.42 in 1949 compared with $4.64 in 1948 and $4.19 in 1947. Price quotations at the beginning of 1949 on "hard-quartz" silica (99½ percent grade), as reported in Oil, Paint and Drug Reporter, were as follows: 325-mesh, carlots, in bags, $15 per net ton, and less than carlots, $20 per ton; and 140-mesh, carlots, in bags, $10 per ton, and less than carlots, $15 per ton. After April 1, these quotations were raised to $20 per ton for 325-mesh, carlots, in bags; $25 for less carlots; and $12 per ton for 140-mesh, carlots, in bags; $17 for less than carlots, and remained at these levels for the balance of the year. A survey of quartz, quartzite, and other silica deposits in North Carolina was published.[23]

Ground Sand and Sandstone.—Sales of ground sand and sandstone in 1949 decreased 12 percent in tonnage and 9 percent in value from the record year 1948 and totaled 610,789 short tons valued at $5,258,464. The average value per ton in 1949 increased to $8.61, compared with revised values for 1948 and 1947 of $8.34 and $8, respectively. Illinois, the largest producing State, accounted for 36 percent of the total sales and showed a 7-percent loss from 1948 output. Production in all other States for which data are shown was less than in 1948, including a small decline for Ohio, Virginia, and West Virginia combined. The larger producing States, other than Illinois, were New Jersey, Ohio, Pennsylvania, and West Virginia.

Ground sand and sandstone sold or used by producers in the United States, 1945–49

[3] California, Missouri, Oklahoma (1949), Pennsylvania, Texas (1948), Washington (1947 and 1949), and Wisconsin.

The chief consumers of ground sand and sandstone in 1949 were the pottery, porcelain, and tile industries (37 percent of the tonnage for which uses were reported), abrasives industries, chiefly cleansing and scouring compounds (23 percent), foundries (13 percent), glass (6 percent), and filler (6 percent). Enamel and miscellaneous comprise the balance of the tonnage for which data were given. Only fillers showed an increase in 1949 over 1948. The distribution by uses in 1949 was based on reports from companies accounting for 93 percent of the total sales.

Ground sand and sandstone sold or used by producers in the United States in 1949, by uses [1]

Use	Short tons	Value	
		Total	Average per ton

Total reported by uses	567,589	4,880,464	8.60

[1] Data represent 93 percent of the industry.

Abrasive Sands.—Considerable tonnages of natural sands with a high silica content are sold for abrasive purposes, such as glass grinding, stone polishing, coating sandpaper, and sand blasting. Sales of these abrasive sands in 1949 totaled 1,080,886 short tons valued at $2,063,866 compared with 1,119,802 tons valued at $2,151,095 in 1948. The 1949 figures include 393,427 tons of blast sand valued at $1,222,513 an increase of 3 percent in both quantity and value compared with 1948. Detailed data regarding tonnages produced in each State appear in the Sand and Gravel chapter of this volume.

SPECIAL SILICA-STONE PRODUCTS

clined [illegible] lowest point of recorded output, and the value was the lowest since 1938. As in recent years, grindstones were reported from Ohio and West Virginia and pulpstones from Washington.

Grindstones and pulpstones sold by producers in the United States, 1945–49

Year	Grindstones		Pulpstones

[1] Bureau of Mines not at liberty to publish figure.

Oilstones and Other Sharpening Stones.—Output of natural sharpening stones was smaller in 1949 than in 1948. The Bureau of Mines is not at liberty to publish the figures. Producing States in 1949 and type of abrasive stones reported from each follow: Arkansas—oilstones and whetstones; Indiana—whetstones and rubbing stones; New Hampshire—scythestones; and Ohio—scythestones, whetstones, and rubbing stones (holystones).

Millstones.—The value of sales of millstones in 1949 was slightly less than half that in 1948 and was the lowest since 1943. No chasers were reported in 1949. States marketing millstones in 1949 were North Carolina (Rowan County) and Virginia (Montgomery County).

Value of millstones and chasers sold by producers in the United States, 1944–49 [1]

Year	Number of producers	Value	Year	Number of producers	Value
1944	3	$9,700	1947	4	$23,189
1945	4	15,018	1948	3	17,733
1946	4	14,780	1949	2	9,400

[1] Produced in Minnesota (1945 only), New York (1944–48), North Carolina, and Virginia.

Grinding Pebbles and Tube-Mill Liners.—The tonnage and value of grinding pebbles sold or used in 1949 dropped sharply compared with 1948. The quantity of tube-mill liners also declined somewhat in 1949, although the realization increased. As in 1948, States from which grinding pebbles were reported in 1949 were: California, Minnesota, North Carolina, Texas, Washington, and Wisconsin. Tube-mill liners were reported from Minnesota, North Carolina, and Wisconsin.

The following companies produced for sale the products indicated: Crystal Silica Co., Los Angeles, Calif., grinding pebbles; Jasper Stone Co., Sioux City, Iowa, liners and grinding pebbles (quarries in Minnesota); Harris Granite Quarries Co., Salisbury, N. C., liners and grinding pebbles; Dezendorf Marble Co., Austin, Tex., grinding pebbles; Mineral Products Co., Seattle, Wash., grinding pebbles; and Baraboo Quartzite Co., Baraboo, Wis., liners and grinding pebbles.

Grinding pebbles and tube-mill liners sold or used by producers in the United States, 1945–49

Year	Grinding pebbles		Tube-mill liners		Total

NATURAL SILICATE ABRASIVES

Pumice and Pumicite.—Output of pumice and pumicite (volcanic ash) in 1949 rose 18 percent compared with 1948 to 716,742 short tons, a record tonnage. The total value declined in 1949 but was higher than in any year except 1948. Pumice has been shipped in increasing quantities into the Middle West and South as an aggregate in lightweight concrete, an outlet that has developed rapidly in recent years. Much of this material has originated in the Southwest.

Pumice and pumicite sold or used by producers in the United States, 1944–49

Year	Short tons	Value	Year	Short tons	Value

[2] Alaska (1948), Arizona (1949), Colorado (1947), Kansas, Montana (1948), Nevada (1949), Oklahoma, Texas, and Utah (1949).

Production of pumice or pumicite was reported from 12 States in 1949 compared with 11 States and Alaska in 1948. New Mexico output nearly doubled, placing that State in first place in rank of producers, and accounted for 49 percent of the total sales. The second largest producing State was California, followed by Oregon and Idaho. Output in Oregon was slightly under that of 1948, and California and Idaho showed fairly large losses. Nebraska increased its output in 1949 compared with 1948. Combined sales of four States—New Mexico, California, Oregon, and Idaho—accounted for 94 percent of all the pumice and pumicite marketed in 1949. The average realization per ton declined to $3.31 compared with $4.12 in 1948 and $4.57 in 1947.

Pumice and pumicite sold or used by producers in the United States, 1947–49, by uses

Use	1947		1948		1949	
	Short tons	Value	Short tons	Value	Short tons	Value
Abrasive:						
Cleansing and scouring compounds and hand soaps	25,266	$323,885	16,005	$245,994	15,926	$188,823
Other abrasive uses	5,800	326,348	4,508	251,828	8,077	320,017

Total	442,552	2,021,880	607,746	2,501,906	716,742	2,369,082

[1] Insecticide, insulation, brick manufacture, filtration, solvents, plastics, paint filler, absorbents, and unspecified.

Pumice and pumicite sold for concrete admixture and concrete aggregate in 1949 increased 20 percent over 1948 and totaled 672,592 short tons. Pumice used for abrasive purposes increased 17 percent and that used in acoustic plaster was over 2½ times that reported in 1948. Tonnages sold for "other uses" declined sharply in quantity and value. "Other uses" included absorbents, insecticides, insulation, paint filler, and miscellaneous. Consumption of pumice and pumicite for abrasive purposes in recent years has steadily decreased in importance, while its use in concrete has shown a very rapid growth. (See fig. 1.)

As reported in Oil, Paint and Drug Reporter, quotations on domestic and imported pumice in 1949 remained at the same levels as in 1948 and were as follows: Domestic coarse ground (sizes 0½, 1, 1½, 2, 3) in bags, ton lots, New York, 3⅝ to 4 cents per pound (Chicago, 4½ cents), smaller lots, 3⅞ to 4½ cents; fine ground, in bags, ton lots, 3⅜ cents per pound, smaller lots, 3⅝ to 4 cents; imported—Italian, silk-screened, fine, in bags, ton lots, 4 cents per pound, coarse, 5½ cents; sun dried, fine, in bags, ton lots, 3 cents per pound, coarse, 4½ cents. Pumice in barrels was quoted at ½ cent per pound higher. No quotations on pumicite are given in the trade press.

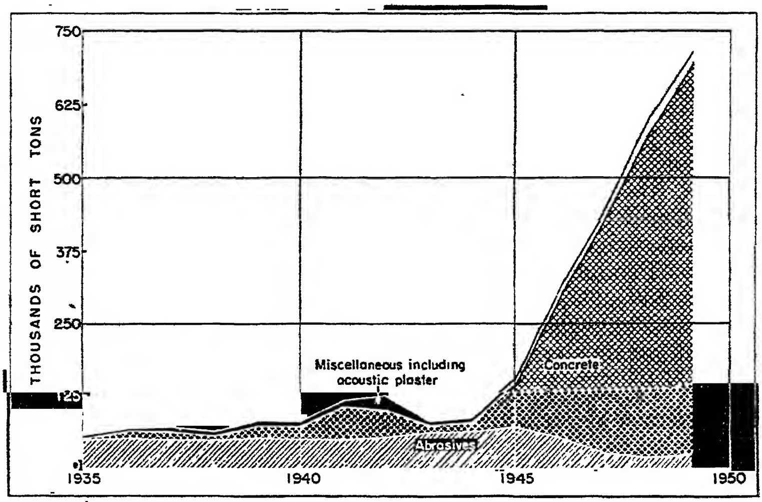

FIGURE 1.—Trends, by uses, of pumice and pumicite sold or used in the United States, 1935–49.

The operations of two plants serving the southern California region were described in the trade press.[24] Descriptions of other plants with photographs of plant and equipment, one in northern California [25] and another in the Idaho-Utah region,[26] were published. A pumice sizing plant in Oregon making aggregate, chicken grits, and soil conditioner was described.[27] A new operation on a large deposit of pumice in Wyoming planned to start production during the early part of 1950.[28]

The volcanic ash deposits in southwestern Oklahoma have been surveyed,[29] and a process was developed for making a bloated product for use as a lightweight construction material.[30] A study of the use of Oregon volcanic ash in the manufacture of glass was authorized by the Oregon State Department of Geology and Mineral Industries.[31] The University of New Mexico is making a survey of the pumice deposits in or near the Los Alamos reservation for the Atomic Energy Commission.[32]

Pumice as a lightweight aggregate continued to be a vital subject and evoked much interest during 1949. Among the articles on this

subject were a general survey of the mineral substances used for this purpose, published by the National Ready Mixed Concrete Association [33] and an investigation of the properties of lightweight aggregates by the National Bureau of Standards.[34] Lightweight insulating concretes also were discussed at length with mention made of the use of pumice for this purpose.[35] Pozzolanic materials including pumice and pumicite, their processing, and their advantages in the making of cement were investigated.[36] Portland pozzolan cement using pumicite has proved satisfactory in the construction of dams.[37]

Garnet.—Production of garnet in 1949 decreased to 6,578 short tons valued at $505,231, the lowest point since 1945 and 18 percent less in tonnage and 14 percent less in value than in 1948. The trend in output (sales) of garnet since 1920 is shown in figure 2. Producers reporting sales in 1949 were: Garnet Mines, Inc., Fernwood, Idaho; Idaho Garnet Abrasive Co., Inc., P. O. Box 1452, Spokane 6, Wash. (deposit near Fernwood, Idaho); Northern Minerals, Inc., Essex, N. Y.; and Barton Mines Corp., North Creek, N. Y. The advantages of using an Akins separator in the processing of garnet included lower milling costs, according to a recent article.[38] A brief description of the production and processing of abrasive garnet by Idaho Garnet Abrasive Co., Inc., in the Emerald Creek area of Idaho was published.[39] Rare Earths, Inc., Grangeville, Idaho, plans to produce garnet as a by-product of its monazite sand operations.[40]

Abrasive garnet sold or used by producers in the United States, 1944–49

Year	Short tons	Value	Year	Short tons	Value
1944	(1)	(1)	1947	8,722	$614,071
1945	6,306	$375,198	1948	8,039	587,797
1946	7,748	570,136	1949	6,578	505,231

1 Bureau of Mines not at liberty to publish figure.

As quoted in E&MJ Metal and Mineral Markets during 1949, the price of New York Adirondack garnet concentrates in grain form was given as $85 per net ton, the same as in recent years.

NATURAL ALUMINA ABRASIVES

Corundum.—Although reported output of corundum in the Union of South Africa, by far the chief world source of supply, was only 3 percent less in 1949 than in 1948, imports for consumption in the United States decreased sharply, totaling only 2,013 short tons in 1949. Difficulties in obtaining large enough shipments of material to meet minimum commercial demand in this country continued and did not allow any sizable increase in the National Stockpile. The United States Government and the American Abrasive Co. both have been attempting to obtain increased production in the Union of South Africa by stabilizing prices to the corundum diggers.[41] In the effort to augment present sources of supply, it is understood that negotiations have been initiated to buy corundum from French Cameroon, and further studies of marginal deposits in Mozambique and Nyasaland have been undertaken.[42] Geologic, geographic, and economic data regarding corundum deposits in the Union of South Africa and their exploitation were presented in a recent article.[43] The manufacture of synthetic corundum in Switzerland and a discussion of its uses were published.[44]

Prices on imported corundum are not quoted in the domestic trade press. Average value (foreign market value) of corundum ore imported in 1949 was $92.56, compared with $83.30 in 1948 and $80.87 in 1947. Quotations on natural corundum grain in 1949, as given in E&MJ Metal and Mineral Markets, remained at previous levels, as follows: Per pound, sizes 8 to 60, inclusive, 8¾ cents; 70–270, inclusive, 9¾ cents; 500, 30 cents; 850, 45 cents; 1,200–1,600, inclusive, 65 cents; and 2,600, 70 cents.

Total (estimate) [1]	3,910	6,207	7,029	5,600	5,680	6,800	3,150	2,500	3,000	2,750

[1] In addition to countries listed, corundum probably is produced in U. S. S. R., but data on production are not available, and no estimate is included in the total.
[2] Data not available; estimate by author of the chapter included in total.
[3] Reported as corundum and emery (believed to be largely emery).
[4] Imports into the United States.
[5] Estimate.
[6] Recovered from tailing dumps.
[7] Less than 1 ton.
[8] Bureau of Mines not at liberty to publish figure, but total includes United States production as measured by sales.

Emery.—Production of emery for sale in 1949 decreased to 4,909 short tons valued at $60,917, or 9 percent less in quantity and 12 percent less in value than in 1948. These figures were the lowest in quantity and value, respectively, since 1941 and 1942. Producers of emery in 1949, as in other recent years, were Joe DeLuca and DiRubbo & Ellis, both of Peekskill, N. Y. Because of its marked resistance to wear, a large part of the output is used as a nonskid agent in concrete floors and steps. The balance is consumed for abrasive purposes, such as the manufacture of grinding wheels, abrasive sticks, and similar products. The sales since 1920 are presented graphically in figure 2. The experience of a saw-manufacturing company in using emery dust was reported.[45]

Emery sold or used by producers in the United States, 1944–49

Year	Short tons	Value	Year	Short tons	Value
1944	6,940	$64,858	1947	5,798	$66,927
1945	7,856	75,977	1948	5,405	69,408
1946	6,188	62,099	1949	4,909	60,917

As quoted in E&MJ Metal and Mineral Markets, the price of domestic first-grade emery ore, f. o. b. New York, was given as $12 per ton during both 1949 and 1948. Average value (foreign market value) of imported Turkish emery ore in 1949 was $13.42 per net ton, com-

[45] Cassels, C. S., Handling Emery Dust in Saw Glazing—Henry Disston & Sons, Inc.: Iron Age, vol. 164, No. 18, Nov. 3, 1949, pp. 94–95.

pared with $10.30 in 1948 and $16.34 in 1947. Grain emery in 1949 (f. o. b. Pennsylvania, in 350-pound kegs) was quoted in E&MJ Metal and Mineral Markets at 10 cents per pound for Turkish and Naxos grain and 6 cents per pound for American grain.

NATURAL CARBON ABRASIVES [46]

Industrial Diamonds.—The value of world sales of industrial diamonds in 1949 dropped 25 percent to £8,468,486 compared with the £11,300,000 sold in 1948, according to the Industrial Distributors (Sales), Ltd., London, the diamond-syndicate selling agency. Imports for consumption in the United States of bort, carbonados and ballas, and diamond dust in 1949 also showed large decreases in both quantity and value. The United States Government continued to make substantial purchases under its stockpiling program. The trend toward the use of smaller and cheaper diamonds in engineering, especially in multiset tools, was reflected in the lower average value of bort per carat of imports—1947, $3.27 per carat; 1948, $3.06; and 1949, $2.76. After devaluation of the pound sterling, prices of South African industrial diamonds were raised 30 percent for drilling stones and crushing bort, 25 percent for tool stones, and 20 percent for common goods.

A description of the building and an outline of the type of research carried forward at the new diamond research laboratory at Johannesburg, Union of South Africa, included a floor plan and a listing of the current projects under investigation. The latter include recovery, utilization, and fundamental research on physical properties of industrial stones and gems.[47] The uses of industrial diamonds in watch manufacture [48] and ceramics [49] in particular were reported.

The position of diamonds in the Union of South Africa and their importance in the general economy of the country were discussed briefly.[50] Gem stones rather than industrial diamonds have been the principal product of the diamond operations in that country. The opening of the Premier and New Jagersfontein pipe mines, scheduled for 1950, will increase the Union's production of good-quality industrials. Extensive mechanization, new equipment, and increased reserves of proved diamond-bearing areas were announced by the chief producer in the Belgian Congo,. the Société Miniére du Beceka.[51] The occurrence and development of the diamond deposits in British West Africa [52] and British East Africa [53] were described. Production, operating companies, and exports of diamonds from Gold Coast were

reported.[54] An interesting account of the discovery, history, and present development of the Diamond Corp. of America property near Murfreesboro, Ark., was published.[55] Another possible source of Arkansas diamonds has been located, according to the Arkansas State Geology Division.[56]

ARTIFICIAL ABRASIVES

The combined tonnage of silicon carbide, aluminum oxide, and metallic abrasives manufactured in 1949 decreased 18 percent in quantity and 24 percent in value compared with 1948. Production of aluminum oxide and shipments of metallic abrasives in 1949 each were substantially less than in the preceding year. On the other hand, production of silicon carbide rose 7 percent in quantity to its second highest year (only 3 percent below the peak year 1943) and topped by 2 percent the previous record realization (1943). The total for aluminum oxide in 1949 included 10,858 short tons of "white high-purity or special" material valued at $1,178,290, compared with 15,706 tons valued at $1,726,093 in 1948, a decrease of 31 percent in quantity and 32 percent in value. The estimated percentage of aluminum oxide used for refractory and other nonabrasive purposes in 1949 was 3 percent compared with 4 percent in 1948, while the similar figure for silicon carbide dropped to 24 percent in 1949 compared with 47 percent in 1948.

Crude artificial abrasives produced in the United States and Canada, 1945–49

Year	Silicon carbide [1]		Aluminum oxide [1] (abrasive grade)		Metallic abrasives [2]		Total	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1945	53,773	$4,238,665	147,016	$9,130,093	146,771	$8,524,073	347,560	$21,892,821
1946	63,849	5,457,903	132,084	8,367,158	111,512	6,387,819	307,445	20,212,880
1947	63,724	5,633,811	160,022	10,158,432	154,191	12,449,855	377,937	28,242,098
1948	63,033	5,874,731	154,972	10,279,583	147,218	15,174,773	365,223	31,329,087
1949	67,539	6,055,763	125,806	8,500,074	104,778	9,312,368	298,123	23,868,205

[1] Bureau of Mines not at liberty to publish data for United States separately. Figures include a small quantity used for refractories and other nonabrasive purposes.
[2] Shipments from United States plants only.

Stocks of metallic abrasives in 1949 increased slightly (2 percent); stocks of aluminum oxide were 45 percent higher than in 1948; and stocks of silicon carbide in 1949 more than quadrupled. There was an 11-percent increase in average annual capacity for silicon carbide production, a small rise in capacity for aluminum oxide, and a small decrease in capacity for metallic abrasives. The ratio of production to annual capacity was considerably lower in 1949, except for silicon carbide which was working at 83 percent of capacity, or only 3 percent less than in 1948. The ratios for aluminum oxide were 53 percent in 1949 and 66 percent in 1948 and for metallic abrasives were 46 percent in 1949 and 61 percent in 1948.

[56] Engineering and Mining Journal, vol. 150, No. 9, September 1949, p. 120.

Stocks of crude artificial abrasives and capacity of manufacturing plants, as reported by producers in the United States and Canada, 1945–49, in short tons

Year	Silicon carbide		Aluminum oxide		Metallic abrasives [1]	
	Stocks, Dec. 31	Average annual capacity	Stocks, Dec. 31	Average annual capacity	Stocks, Dec. 31	Average annual capacity
1945	4,347	72,000	31,933	233,300	10,433	209,360
1946	5,339	71,679	27,072	232,889	6,524	211,407
1947	3,524	72,350	32,977	233,500	9,987	245,479
1948	5,387	73,250	34,177	233,500	9,907	240,129
1949	21,964	81,121	49,505	237,072	10,144	231,650

[1] Figures pertain to United States plants only.

Production of silicon carbide and aluminum oxide largely is concentrated in areas of plentiful and relatively inexpensive water power, especially in the Niagara Falls region of Canada and the United States and in Quebec; some aluminum oxide, however, is produced in Alabama. Two new silicon carbide plants under construction during 1948 were being operated in 1949—that of the Carborundum Co. at Vancouver, Wash., and that of the Electro Refractories & Alloys, Canada, Ltd., at Cap-de-la-Madelaine, near Three Rivers, Quebec, Canada. It was reported, also, that Norton Co., Worcester, Mass., has purchased a plant at Cap-de-la-Madelaine from Durham Chemicals, Ltd., for conversion to the manufacture of silicon carbide.[57]

Statistics of metallic abrasives include data for steel shot and grit but not steel wool, and pertain to shipments from United States plants only. The same firms reported sales in 1949 as in 1948 (18 companies with 19 plants). The three largest producing States again were Ohio, Michigan, and Pennsylvania. Metallic abrasives also were produced in 1949 in Illinois, Massachusetts, New Hampshire, and New York.

A description of the properties of aluminum oxide porous filter mediums was published.[58] The utilization of silicon carbide, aluminum oxide, and boron carbide in ceramics was described.[59] Cheap hydroelectric power and a growing market presage a sizable installation of artificial abrasives capacity in the Pacific Northwest region, according to a recent survey.[60]

MISCELLANEOUS MINERAL ABRASIVE MATERIALS

In addition to the natural and manufactured abrasive substances for which data are included herein, many other mineral materials are used for abrasive purposes. A number of oxides, including tin oxides, magnesia, iron oxides (rouge and crocus), cerium oxide,[61] chromium oxide, and manganese oxide, are employed as polishing agents. A zirconium silicate claimed to be useful for polishing optical glass has

[57] Moody's Industrials, 1949 Edition, p. 479; Chem. Eng., vol. 56, No. 3, March 1949, p. 248.

[60] Block, Ivan, Pacific Northwest—1960: Chem. Eng., vol. 56, No. 9, September 1949, p. 111.
[61] Davis, H. M., and Wayman, R. S., Manufacture of Ceria Polish: Canadian Chem. Process Ind., vol. 29, 1945, pp. 230–231; Jour. Am. Ceram. Soc., vol. 32, No. 8, August 1949, p. 193 (abs.).

been patented.[62] Also intended as a glass polishing medium is a recently patented abrasive made by calcining kaolin at about 2,200°F. in the presence of quicklime.[63] Certain carbides, such as boron carbide and the cemented carbides[64] which include tantalum carbide, titanium carbide, and tungsten carbide, have been used for their abrasive properties or because of their extreme hardness or durability. Other substances with abrasive applications include finely ground and calcined clays (ball clays, china clays, fire clays), lime, talc, ground feldspar, river silt, slate flour, and whiting.

FOREIGN TRADE[65]

Imports.—The total value of imports for consumption of both natural and artificial abrasives declined sharply in 1949 compared with 1948. Imports of diamond bort, carbonados and ballas, and diamond dust were substantially less than in 1948. Receipts of corundum ore and unground flint, flints, and flintstones decreased 44 and 33 percent, respectively. Imports of pumice increased somewhat, and emory ore and manufactured diamond bort showed large percentage gains over 1948, although they were considerably under 1947 levels. Imports of crude fused aluminum oxide in 1949 dropped 27 percent and silicon carbide 22 percent compared with 1948.

Exports.—The value of exports of natural and artificial abrasives in 1949 rose 14 percent compared with 1948. Due to a change in tariff classifications, it is not possible to show over a 5-year period data for items other than grindstones and pulpstones, diamond dust, and diamond grinding wheels. Exports of grindstones and pulpstones and diamond grinding wheels were smaller than in 1948, while diamond dust showed a moderate increase in caratage.

In 1949 the classification of "other natural, artificial, and metallic abrasives, manufactures and products" comprised natural abrasives and products valued at $4,072,648; manufactured or artificial abrasives and products valued at $9,056,436; manufactured grinding wheels except diamond wheels valued at $3,219,689; abrasive pastes, compounds, and cake valued at $97,059; and steel abrasives valued at $463,624. Exports of fused aluminum oxide and fused silicon carbide, crude and grain, in 1949 totaled 29,960 short tons valued at $3,880,078 and 6,315 tons valued at $2,056,813, respectively. Exports of abrasive paper and cloth of manufactured abrasives amounted to 70,882 reams valued at $2,248,615 compared with 89,609 reams valued at $1,534,398 of abrasive paper and cloth made of natural abrasives.

Aluminum

By Richard H. Mote and Horace F. Kurtz

GENERAL SUMMARY

DOMESTIC primary aluminum output in 1949 decreased slightly from the record peacetime level established in 1948. Labor strikes closed three electrolytic reduction plants in the latter part of 1949 and were more responsible for offsetting the increased rate of production that characterized the beginning of the year than the chronic power shortages. Unlike most other industries, demand, which fell during spring and summer as a result of a general business recession and a lowering of inventories by aluminum consumers, had little effect on operation of most aluminum reduction plants. Secondary recovery added less to the supply of aluminum than in recent years.

Salient statistics of the aluminum industry, 1940–44 (average) and 1945–49

	1940–44 (average)	1945	1946	1947	1948	1949

[1] Revised figure.

Apparent consumption of virgin aluminum declined 4 percent despite an increase to approximately 48,000 tons in net imports. As in all years since the conclusion of World War II, building products led the field of uses. Base prices of primary pig and ingot remained unchanged at 16 and 17 cents per pound, respectively, throughout 1949.

World production increased from an estimated 1,268,000 metric tons (revised figure) in 1948 to 1,308,000 tons in 1949. Output in Japan and Bizonal Germany gained substantially.

Aluminum ores, alumina, and aluminum salts are discussed in the Bauxite chapter of this volume.

PRODUCTION

Primary.—Domestic production of primary aluminum declined approximately 20,000 short tons to 603,462 tons in 1949. Aluminum output was high, however, compared with the over-all level of industrial production. The index of total production [1] dropped 8 percent

[1] Federal Reserve Bank indexes of physical volume of industrial production, 1935–39 equals 100.

from 192 in 1948 to 176 (preliminary) in 1949; but the index for aluminum production, calculated on the same base period, decreased from 498 to 482 or only about 3 percent. Because of the desirability of utilizing available power and maintaining optimum operating levels, production of pig aluminum at the reduction plants was not an immediate function of demand; on the other hand, special limiting factors, such as labor strikes and power curtailments, which did not affect most other industries, reduced output of aluminum in 1949.

Production of primary aluminum in the United States in 1949, by months

Month	Short tons	Month	Short tons	Month	Short tons
January	53,356	May	56,909	September	49,742
February	49,749	June	54,184	October	45,790
March	54,852	July	55,777	November	35,865
April	54,076	August	52,001	December	41,161

Primary production during each of the first 7 months of 1949 exceeded that in the corresponding month of 1948 and in May reached a monthly peak for the postwar period. Labor-management disputes, resulting in plant shut-downs, were the most significant factor adversely affecting production during the latter part of 1949. The first labor strike, beginning in August and terminating late in September, lasted 7 weeks and forced closure of Reynolds Metals Co. Hurricane Creek alumina plant and the Jones Mills facilities, both in Arkansas. A second strike, extending from October 17 to December 7, closed nine Aluminum Co. of America plants, including the huge reduction plant at Alcoa, Tenn., and a smaller operation at Badin, N. C. Power shortages in the Northwest also curtailed output during the final quarter of the year.

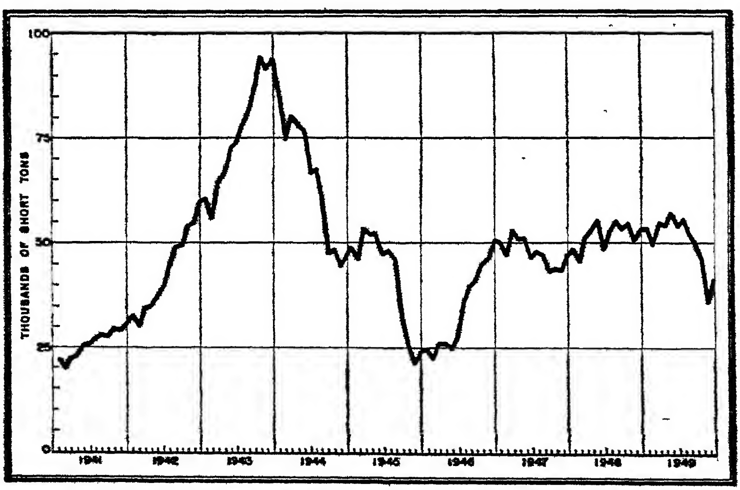

FIGURE 1.—Production of primary aluminum in United States, 1941–49. Data for 1941–July 1946 from War Production Board and Civilian Production Administration; thereafter, from reports to Bureau of Mines.

At the end of February, Aluminum Co. of America closed and dismantled its obsolete smelting plant at Niagara Falls, N. Y. Its new plant, with greater capacity, located at Point Comfort, near Port Lavaca, Tex., was nearly completed by the end of 1949. This plant, the first reduction plant constructed since the close of World War II, was described in the 1948 chapter of this series. Until the spring of 1949, Reynolds had operated only two pot lines or half the capacity of its plant at Jones Mills, Ark., owing to power shortage. Production from the third pot line was begun in April but was not resumed after the strike was settled. Both Reynolds and Aluminum Co. of America conducted surveys as to the feasibility of constructing facilities in British Columbia and Alaska, utilizing electrical energy from British Columbia where abundant potential water power is available.

Except for dismantling the Aluminum Co. of America plant at Niagara Falls, the productive capacity of the industry in 1949 was distributed among the producers unchanged since 1946. At the end of 1949, this company operated about 310,000 tons, or 49 percent of the total 630,000 tons operable rated annual reduction capacity; Reynolds, 190,000 tons or 30 percent; and Kaiser Aluminum & Chemical Corp., whose name was changed from Permanente Metals Corp., 130,000 tons or 21 percent.

The General Services Administration progressed further in 1949 with its program for disposal of Government-owned aluminum plants and facilities. Early in June, GSA announced the sale to Kaiser of the rod and bar mill at Newark, Ohio. Sale of the alumina plant in Baton Rouge, La., and the Mead reduction plant and Trentwood rolling mill in Spokane, Wash., in July completed transfer to private ownership of all surplus Government alumina and aluminum plants operated by Kaiser. In April, GSA sold the aluminum extrusion plant at Grand Rapids, Mich., to Reynolds. Five other plants, including the alumina plant at Hurricane Creek, Ark., the reduction plants at Jones Mills, Ark., and Troutdale, Oreg., the rolling mill at Chicago, Ill., and the extrusion plant at Phoenix, Ariz., were bought by Reynolds in December. Final sale of the Government-constructed St. Lawrence plant in New York to Alcoa was withheld through 1949 pending outcome of the United States Department of Justice monopoly charge in litigation against the company.

Although no new reduction plants were operated during 1949, primary producers expanded and improved facilities in other phases of production. Kaiser entered the foil industry by installing German machinery at its redesigned Permanente, Calif., plant and also added new rolling equipment at Trentwood and wire and cable facilities at Newark. Alcoa constructed a new plant at East St. Louis, Ill., for the production of fluoride chemicals, nearly completed a rod, wire, and cable mill at Vancouver, Wash., and began full operation of its Davenport, Iowa, sheet and plate rolling mill. A large expansion program was begun at Listerhill, Ala., by Reynolds to increase its capacity for producing foil, bar, rod, wire, and cable.

Shipments of aluminum wrought products and castings in 1949, as reported by the United States Department of Commerce, totaled 731,288 tons, compared with 1,032,303 tons the preceding year. Plate,

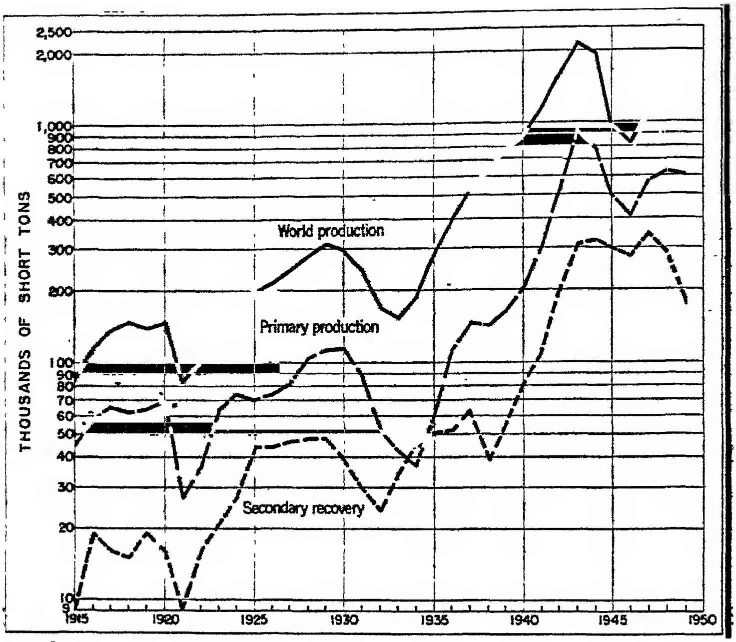

FIGURE 2.—Trends in world and domestic primary production and domestic secondary recovery of aluminum, 1915–49.

sheet, and strip comprised 68 percent of the 578,979 tons of wrought products, but rolled structural shapes, rod, bar, and wire was the only classification that increased in 1949. Of the 152,309 tons of castings reported shipped, 35 percent were sand castings, 34 percent permanent mold, 29 percent die, and 2 percent all other.

Secondary.—Recovery of 180,762 tons of aluminum derived from secondary material supplemented primary supplies in 1949 but was over 100,000 tons short of the 1948 total from this source. Secondary ingot prices, which where considerably higher than those for corresponding grades of primary ingot at the beginning of 1949, were sharply reduced by mid-summer and recovered only partly by the end of the year.

Detailed information regarding secondary aluminum in 1949 is given in the Secondary Metals—Nonferrous chapter of this volume.

CONSUMPTION AND USES

The apparent consumption of primary aluminum in 1949 totaled 635,956 tons, as computed by adding production and net imports and adjusting for producers' stock changes. This total was 4 percent less than the 665,875 tons (revised figure) used in 1948. However, as pointed out in the 1946 chapter of this series, the large importation and subsequent holding of Canadian aluminum by the Office of Metals Reserve greatly distorted apparent consumption from 1944 through 1948; and, for the purpose of presenting a truer picture of domestic

aluminum consumption, a modified set of figures was evolved, presented in the accompanying table, taking into account releases of Canadian aluminum from Reconstruction Finance Corporation inventories. This metal was completely disposed of by the end of 1948.

Apparent consumption of aluminum in the United States, 1940–44 (average) and 1945–49, in short tons

Year	Primary aluminum				Secondary aluminum recovered from old scrap	Total consumption
	Sold or used by producers	Imports (net)	Apparent consumption	Modified apparent consumption [1]		
1940–44 (average)	548,013	137	548,150	533,439	37,309	570,748
1945	468,836	328,216	797,052	696,750	27,311	724,061
1946	435,964	25,913	461,877	575,687	90,535	666,222
1947	570,923	[2] −46,694	[2] 524,229	[2] 571,789	163,847	[2] 735,636
1948	625,834	[2] 40,041	[2] 665,875	[2] 684,575	95,648	[2] 780,223
1949	587,532	48,424	635,956	635,956	44,596	680,552

[1] Apparent consumption modified by changes in stocks held by the Office of Metals Reserve.
[2] Revised figure.

Consumer demand for primary aluminum far exceeded the productive capacity of the industry during the early part of 1949. The huge backlog of orders for aluminum maintained relatively firm market conditions throughout most of the year's first quarter. Thereafter, as in the case of most other metals, demand fell rapidly, producers' stocks expanded, and metal shortages quickly disappeared. Consumers, aware of the growing availability of metal and fearing losses from possible market price declines, reduced inventories and canceled many previous orders, particularly on sheet aluminum. It should be noted that the beginning of this downward spiral in aluminum demand coincided with abandonment of plans for a 70-group air force. Market conditions reached a low point in midsummer, improved gradually thereafter, and were quite favorable for producers by the end of the year.

In 1949, building products led the field of aluminum consumption, a position that has been retained since the end of World War II. However, based on reports from the three producers of primary metal, most significant gains were made in uses for power transmission and transportation. Shipments of aluminum ingot and mill products by the Aluminum Co. of America in 1949 were distributed as follows (comparable 1948 figures in parentheses): Building products, 18 percent (18 percent); transportation (all forms), 18 (13); power transmission (conductors), 8 (6); household appliances, 7 (9); cooking utensils, 6 (9); machinery (general and electrical), 4 (4); shipments to fabricators for further processing, 25 (25); and all other uses, 14 (16).

The leading forms of consumption in building products in 1949 were insulated panels and corrugated roofing and siding sheet. A new type of aluminum curtain wall—aluminum panels backed by thin lightweight slabs—was introduced during the year. Wider diversification in construction products was evidenced by improvements and new developments in aluminum ceilings, window frames, chimneys, and

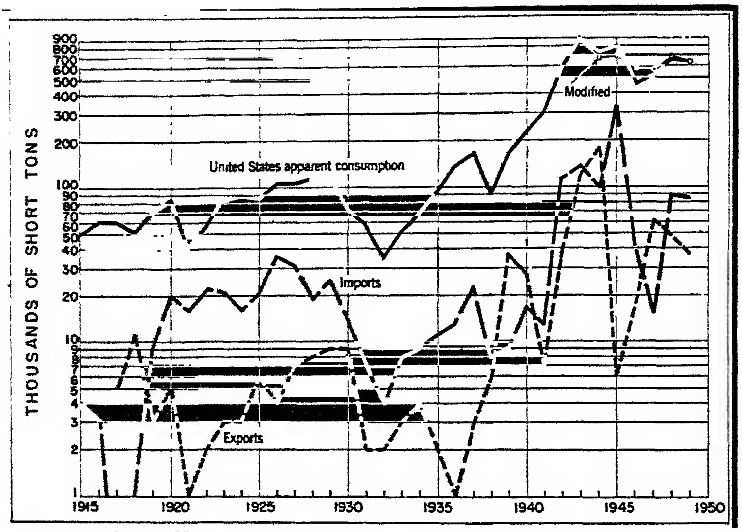

FIGURE 3.—Trends in imports, exports, and apparent consumption of aluminum, 1915–49.

bridges. Orders for over 25,000 aluminum grain bins for storing the Nation's large harvest provided a major outlet for aluminum.

A pronounced shift in the application of aluminum within the field of transportation developed, resulting from the expanded military aircraft procurement program. Whereas motor vehicles previously consumed about two-thirds, it was estimated that over half of the 1949 total for transportation was consumed in aircraft. Among the new aluminum products introduced were forged aluminum truck and trailer wheels and variations of extruded floor systems and other parts for these vehicles. Manufacturers have found motor-transport operators demanding weight saving, reduced maintenance, and other advantages accruing from the use of aluminum. Increased consumption in automobiles was also indicated by the increasing substitution of aluminum in a wide range of parts, chiefly castings. More aluminum was consumed in railroad tank cars in 1949 than in any other year, and new designs in certain passenger units also utilized large quantities.

A contract announced early in 1949 between Reynolds Metals Co. and the Wisconsin Electric Cooperative for the purchase of large quantities of power cable emphasized the growing importance of aluminum for use in electric transmission facilities. All leading producers of wire and cable progressed with plans for increasing production and thereby relieving the long continued shortage of conductor.

Consumption of aluminum foil for insulation and packaging expanded tremendously in 1949, and significant advances were also made in the use of irrigation pipe. Many other applications showed increasing importance, including such diverse products as paints, seamless cable sheathing, fasteners, tread plates, screens, tubing for heat exchangers, and television antennae. Late in the year, the Federal Power Commission approved the first experimental use of aluminum to replace steel in a gas pipeline.

STOCKS

Inventories of pig aluminum at reduction plants totaled 29,101 tons on December 31, 1949, compared with 13,171 tons at the end of 1948. From the end of June through October, however, stocks exceeded 45,000 tons or about 1 month's production. Data on consumers' inventories were not available.

On November 17, 1949, the Munitions Board added aluminum to the list of strategic materials to be stockpiled. No metal was purchased during 1949, but provisions were made to stockpile aluminum received from other Government agencies. In conjunction with this program, the General Services Administration agreed to accept aluminum from Reynolds Metals Co. and Kaiser Aluminum & Chemical Corp. toward payment for wartime aluminum production facilities which they have acquired. Funds advanced to Reynolds by the Economic Cooperation Administration for developing bauxite mining in Jamaica will also be repaid with aluminum.

PRICES

The base price of 30-pound 99-percent-plus virgin aluminum ingot remained throughout 1949 at 17 cents per pound, f. o. b. shipping point, the price established October 11, 1948. The price for primary pig was also unchanged at 16 cents a pound. An important factor in the astonishingly rapid acceptance of aluminum by many consumers over the past quarter of a century has been the downtrend of prices before World War II and their stability since October 1941. Since 1930, the two 1-cent increases in 1948, which were considered necessary to relieve the pressure of greatly increased costs, have been the only times base prices have risen, in contrast to widely fluctuating prices of most competitive materials. Slight readjustments in pricing some products of aluminum were made during 1949.

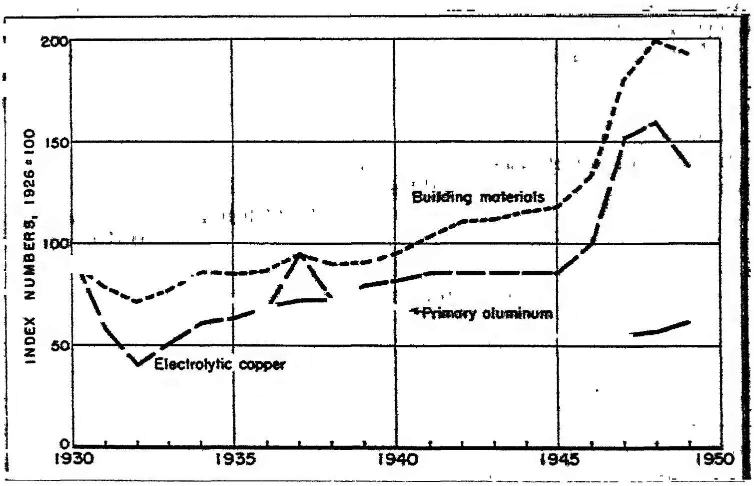

FIGURE 4.—Trends in average quoted prices of aluminum, copper, and building materials, 1930–49. Index numbers computed for electrolytic copper and primary aluminum, 99 percent pure, from prices reported by American Metal Market. Data for building materials from the Bureau of Labor Statistics.

TECHNOLOGY

Numerous technologic advances announced during 1949 pointed toward future expansion in aluminum consumption. In addition, new research laboratories were constructed by primary aluminum producers at East St. Louis, Ill., and Spokane, Wash. Among the many developments, a new general-purpose aluminum sheet alloy, 150S, appeared in the market. In the casting field, the successful production of a large, one-piece, inner door-frame aluminum die casting, to replace the multiple steel stamping and assembling operations formerly used, foretold wider use of aluminum in automobile bodies. A plaster casting process that would enable production of intricate aluminum castings with close tolerances and unusually high surface smoothness was also introduced.

Investigations[2] of three procedures for solid-phase bonding of aluminum alloys to steel were disclosed late in 1949. A new process for applying aluminum to steel to prevent corrosion was also developed. The procedure essentially consists of passing steel strip through an electrolytic bath, where it receives an iron coating, heating in a furnace to about 850° F., and finally rolling under high pressure between two strips of aluminum foil.

The many advancements in finishing and enameling brought forward during 1949 included development of a satisfactory vitreous enamel[3] for aluminum and its alloys. In the process, the frit-based enamel is furnace-fired on aluminum strips, sheetings, and castings.

FOREIGN TRADE[4]

Foreign trade in aluminum, as indicated by total values, declined approximately 18 percent in 1949. Net imports of metal (excluding scrap and manufactures) increased from 40,041 tons in 1948 to 48,424 tons in 1949. About 86 percent, or 72,892 tons, of the 1949 receipts came from Canada, predominantly in crude form, 5,851 tons from United Kingdom, 4,467 from Italy, 1,152 from Norway, and 844 from nine other European and two Asiatic countries. Shipments of sheets, plates, bars, etc., chiefly from United Kingdom, increased, reaching the highest level ever recorded (quantities of semicrude aluminum were first reported separately in 1921). Imports of aluminum-base scrap in 1949 totaled only slightly more than half those of the preceding year. Shipments from Germany, which replaced Canada as the leading source of foreign scrap, totaled 9,321 tons, and those from the United Kingdom 6,559 tons; the remaining 24,240 tons came from 36 other countries. The actual quantity of manufactures imported was not recorded, but their total value increased 79 percent over 1948. The tariff rates on aluminum in 1949 were as follows: Crude—2 cents per pound, scrap—1.5 cents per pound (duty suspended until June 30, 1949), and semifinished—3 cents per pound.

[6] Quantity not recorded.

Exports of aluminum (excluding scrap and manufactures) declined to 36,782 tons in 1949 from 49,108 tons (revised) in 1948. Shipments classified as ingots, slabs, and other forms of crude metal gained during 1949, but exports of plates, sheets, bars, etc., decreased for the second successive year. Crude aluminum was shipped to 23 countries; however, Germany received 4,602 tons or 57 percent of the total. Of the semicrude exported, 9,339 tons went to the Republic of the Philippines, 5,957 tons to Venezuela, and the remainder to 84 other countries. Although validated licenses were still required for shipments and applications were still screened, the Commerce Department removed export quota restrictions on aluminum plate, sheet, and strip for the third and fourth quarters of 1949. Only five countries purchased aluminum-base scrap from the United States during 1949: Haiti received most of the solids, and United Kingdom was the chief recipient of borings, turnings, and dross. The value of aluminum manufactures exported in 1949 declined 19 percent.

WORLD REVIEW

World production of aluminum increased approximately 3 percent to 1,308,000 metric tons in 1949. Although output declined slightly in United States and Canada, which comprised two-thirds of the total, significant increases were recorded in Japan, Germany, Norway, Austria, and Switzerland.

World production of aluminum, by countries, 1943–49, in metric tons

[7] April to June, inclusive.
[8] Preliminary figures.

Austria.—Power shortages in Austria continued to hamper production of aluminum by delaying reopening of the Ranshofen plant until April. However, greater allocation of power in the third quarter permitted operation of larger capacity than was originally proposed. Plans were under way for expanding fabrication facilities near this plant. Output from the smaller plant at Lend, which has its own power plant and was not subject to power restrictions, increased to over 5,000 tons. Austrian demand for aluminum was reported to have increased in 1949.

Canada.—Since conclusion of World War II, Canada has produced approximately one-quarter of the world's primary aluminum ingot. Low-cost hydroelectric power has enabled the Aluminium Co. of Canada, the only Canadian producer, to maintain a position as the leading supplier of metal on the international market, particularly for consumption in Great Britain and United States.

All five reduction plants, including the largest in the world at Arvida in the Saguenay Valley, are in the Province of Quebec. The Arvida, Isle Maline, and Shawinigan Falls plants provided all of the 1949 output; the La Tuque and Beauharnois plants have not operated since 1945. Drought conditions, with a resulting shortage of water for generating power, retarded operations in the first quarter of 1949, and in September portions of the Arvida and Shawinigan Falls plants were closed down because of unstable markets. Proposals were discussed for obtaining additional power for the Saguenay area from the Peribonka River.

Despite a 10-percent devaluation of the Canadian dollar in September, the price of aluminum ingot was unchanged at 15.5 cents per pound. In United States currency exchange this was equivalent to a price reduction of 1.5 cents and meant that Canadian ingot could be sold to the United States at 14 cents plus duty.

Preliminary surveys to establish huge power facilities for aluminum reduction in British Columbia were conducted by the Aluminium Co. of Canada in 1949. By the end of the year, the company had secured approval of a license to develop water power on the Nechako and Nanika Rivers. According to tentative plans, 1 million to 1.5 million horsepower could be developed. Two United States firms were also considering projects of nearly the same magnitude.

France.—The total capacity of French reduction works was rated at 95,000 metric tons, and plans for an additional 30,000 tons may be realized by 1953. All plants are located in either the Alps or Pyrenees and controlled largely by Pechiney but also Ugine interests. Before the last war, abundant bauxite and power in France had led to development of a nearly self-sufficient aluminum industry that normally exported large quantities of metal. Since then, power shortages have forced strict rationing from the nationalized power plants. Aluminum plants have operated at full capacity only during the summer, and these interruptions have resulted in high costs, despite excellent efficiency for most equipment.

Germany.—The governments of the three zones in Western Germany agreed to permit production of primary aluminum from plants totaling 85,000 metric tons theoretical capacity. It was decided to continue operations at Lünen, which was reactivated in 1949, reduce capac-

ity at Rheinfelden and Töging, and dismantle the Erftwerk Grevenbroich smelter. Although poor power conditions, low domestic demand, and large stocks of aluminum tended to limit production during 1949, output increased considerably over the previous postwar years. The price of German aluminum at the close of the year was quoted at D. M. 173 per 100 kilograms.

In the Russian Zone of Germany, only the plant at Bitterfeld was known to have operated in 1949, but reports indicated reopening of facilities at Lauta was being considered.

Hungary.—Planned aluminum production of 12,000 metric tons was not attained in Hungary, as output declined in 1949, owing largely to unavailability of low-cost electrical energy. Hungary has an abundance of bauxite, yet is forced to import cryolite and cheap anode material for reduction to aluminum. Development of the aluminum industry is aimed in three directions: Reducing cost by developing byproducts of alumina; improving aluminum fabrication technology; and expanding usage through substitution for scarce materials.

India.—In 1949 the Indian Parliament passed legislation to protect its two aluminum producers, Indian Aluminium Co. and Aluminium Corp. of India, through import duties and subsidies. Less than one-third of the 1949 demand was met by domestic producers, as labor strikes, lack of petroleum coke, and power restrictions prevented realization of expected output.

Italy.—Shortages of electricity in 1949 retarded production of aluminum in Italy, and exports were greatly reduced. The price of Italian ingot was quoted at 350 lire per kilogram at the close of the year.

Japan.—Production of aluminum in Japan increased threefold during 1949. Although occupational authorities limited actual output to 25,000 metric tons, an annual goal of 25,800 tons was envisioned. Under the proposed target, 14,500 tons were to be produced by Nippon Keikinzoku at Kambara, 6,000 tons by the Sumitomo company at Niihama, and 5,300 tons by Showa Denko at Kitakata. Japan's primary plants relied on bauxite from Indonesia and a domestic fabricating industry with a capacity in excess of the 1949 rate of reduction.

Norway.—With reactivation of facilities damaged during World War II, aluminum production in Norway has risen each year since 1945. Norwegian producers announced plans for increasing reduction capacity to surpass the record output of 1949. Production of a special high-grade aluminum, 99.996 percent pure, at the Vigeland plant was also reported.

Sweden.—Mainly to encourage construction of new primary capacity despite high-cost power, the Swedish Government decided to subsidize aluminum production up to 8,000 metric tons per year, equivalent to about half of domestic demand.

Switzerland.—Aluminum was produced at all four plants in Switzerland during 1949, but imports in bulk form gained slightly while exports declined. An unusual investment of foreign capital within the United States was disclosed by the announcement of Aluminum Foils, Inc., a wholly owned subsidiary of the Swiss Aluminum Co., of plans for erecting a new foil mill at Jackson, Tenn.

United Kingdom.—The aluminum-fabricating industry in United Kingdom, which grew extraordinarily during World War II, has maintained a surprisingly high level of activity since then. Total consumption of ingot in 1949 was approximately the same as in the foregoing year, notwithstanding variations in demand resulting from seasonal and price changes. Consumers experienced little difficulty in obtaining enough aluminum, mostly Canadian in origin, through the only buyer and seller, the Ministry of Supply. Reports that the Government was lowering dollar expenditures for Canadian aluminum were not substantiated by the volume of imports in 1949. Since the war, primary output by the only domestic producers, British Aluminium Co., and Northern Aluminium Co., has been consistently near 30,000 metric tons annually. A future shortage of ingot derived from British secondary sources was indicated by the rapid exhaustion of aircraft scrap.

Prices of 99- to 99.5-percent virgin aluminum ingot in United Kingdom advanced from £87 to £90 per long ton on April 1, and to £93 on August 15. Following devaluation of the British pound in the latter part of September, the price was adjusted to £112; but the increase did not equal the full devaluation, and the selling price of ingot in United Kingdom was brought closer to that of Canadian ingot. The extent to which the Ministry of Supply has had to equalize the high-cost British metal with the Canadian has been a subject of frequent speculation but has not been reported precisely. Chiefly resulting from tariff negotiations at Annecy, it was decided to abolish the 10-percent import duty on unwrought aluminum, effective January 1, 1950.

Yugoslavia.—Yugoslavia has undertaken to develop an aluminum industry to utilize its large production of bauxite. Construction of reduction plants at Strnisce and Mostar have been proposed, the former to be completed by 1951. The Lozovoc plant near Sibenik, built in 1937 with a capacity of 3,000 metric tons, was destroyed during the war. Rebuilt in 1946, the plant has since produced aluminum for the aviation, automobile, and can-manufacturing industries.

Antimony

By Samuel A. Gustavson and Mary E. Trought

GENERAL SUMMARY

A GENERAL business recession in the latter part of 1949 and consumer resistance to high prices of antimony resulted in a downward trend of the antimony industry from 1948. Decreases in the primary antimony industry were: Domestic mine output, 75 percent; domestic smelter production of metal, oxide, and sulfide, 43 percent; consumption, 25 percent; and industry stocks, 36 percent. Imports of ore, metal, and needle antimony decreased 45 percent. Secondary production was down 16 percent. Quoted prices for antimony in all forms recorded a general decline for the first time since price controls were removed November 9, 1946.

New supply of primary antimony available for consumption during 1949, in terms of recoverable metal,[1] was 11,947 short tons. A breakdown of this supply shows domestic antimony ores contributed 1,505 tons; domestic silver and lead ores 1,214 tons; imports for consumption 8,832 tons; and recovered from foreign lead ores 396 tons. The imported antimony arrived as follows: As metal 1,853 tons; recoverable in ores and concentrates 6,875 tons; in needle antimony 57 tons; and in oxide 47 tons. New supply from secondary sources was 18,061 tons.

Estimated total consumption of antimony in the United States in 1949 was 31,515 tons, comprising 13,454 tons in primary and 18,061 tons in secondary material.

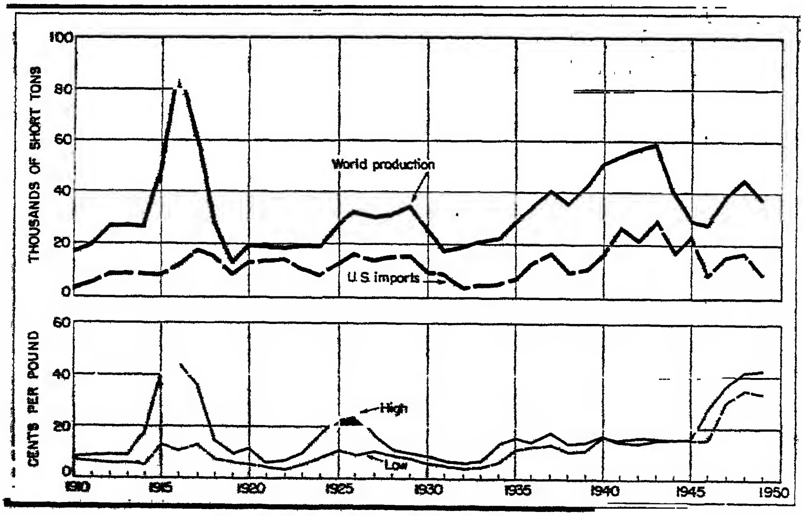

FIGURE 1.—Trends in world production, United States imports, and New York price of antimony, 1910–49.

[1] A factor of 92 percent of the content was used to determine quantity of metal recoverable from antimony ores and concentrates shipped to smelters.

Primary antimony consumed in the manufacture of finished products in 1949 totaled 11,844 tons. This figure includes losses of 314 tons in certain intermediate smelting and refining operations. There are no loss allowances, however, where antimonial materials are consumed in making finished products without intermediate processing in the United States, as when foreign metal or foreign or domestic ore is consumed.

In addition to the 11,844 tons accounted for above, 1,610 tons of primary antimony were recovered, chiefly as antimonial lead, from domestic and foreign silver and lead ores available for consumption. Consumption data for this material are not available. However, to obtain an estimated total consumption of primary antimony, this output should be added to bring the total primary antimony consumed in 1949 to 13,454 tons.

Secondary production and shipment of antimony recovered chiefly in lead base alloys at secondary plants, including antimony from scrap at primary lead refineries, was 18,061 tons.

War Production Board General Preference Order M-112, as amended, was revoked March 25, 1949.

Salient statistics for antimony in the United States, 1940–44 (average) and 1946–49

DOMESTIC PRODUCTION

MINE PRODUCTION

In 1949 shipments of antimony ores and concentrates totaled 5,260 short tons containing 1,636 tons of antimony, of which 1,505 tons are estimated as recoverable. In addition, 1,214 tons of antimony were recovered from silver or lead ores at primary lead refineries, chiefly as antimonial lead. Compared with 1948, the 1949 output of antimony from antimony ores and concentrates decreased 75 percent and from silver and lead ores 45 percent. The chief reasons for these decreases were lack of buying by consumers in resistance to high prices and reduced buying by dealers and refiners who wished to reduce their inventories of high-cost antimony.

Antimony-bearing ores and concentrates produced in the United States, 1940–44 (average) and 1945–49 in short tons

Year	Gross weight	Antimony content		Year	Gross weight	Antimony content	
		Quantity	Average percent			Quantity	Average percent
1940–44 (average)	8,370	2,969	35.7	1947	20,020	5,316	26.6
1945	14,966	1,930	12.9	1948	16,239	6,489	40.0
1946	13,962	2,505	17.9	1949	5,260	1,636	31.1

Alaska.—About 195 tons of ores averaging over 50 percent antimony were produced at four mines in Alaska in 1949, but only 74 tons containing 87,780 pounds were shipped, all by Earl Pilgrim from the Stampede mine in the Seward Peninsula.

Idaho.—Bradley Mining Co., the principal producer of antimony in the United States, ceased mining antimony ore April 1, 1949. The company began operation of its new smelter at Yellow Pine, Idaho, in 1949. Roasting units were started July 18 and the electric furnace, August 1. Hermada Mining Co. operated its mine in Elmore County. The ore is concentrated at the Tolache Mines, Inc., plant in Atlanta, Idaho. Concentrates produced in 1949 totaled 186 tons containing 223,200 pounds of antimony, of which 96 tons containing 115,200 pounds of antimony were shipped. Considerable antimony is recovered from silver ores produced by the Sunshine Mining Co., Shoshone County. This output is reported as antimony in antimonial lead produced at primary lead refineries. A small quantity of antimony was also recovered from silver ore shipped by Golden Age mine in Boise County.

Nevada.—Antimony ores containing a total of 108 tons of antimony were shipped from Nevada mines in 1949. The principal shippers were John M. Heizer and Ott F. Heizer, operating antimony mines in Pershing County. G. A. Peterson, operating the New Potosi mine in Mineral County, shipped 806 tons of lead ore averaging about 3.84 percent antimony to lead smelters at Midvale, Utah, and Selby, Calif. Recovery of antimony from this lead ore is shown in output of antimonial lead from primary lead refineries.

Other States.—Antimony ores containing a total of 6 tons of antimony were received at antimony smelters (from Oregon, 4 tons and Washington, 2 tons). No shipments of antimony ore were reported from mines in other States in 1949. Reports of investigations describing the Coyote Creek antimony deposits, Garfield County, Utah, and of Antimony Peak, Kern County, Calif. were published.[2]

SMELTER PRODUCTION

Primary.—Antimony smelters in the United States produced metal, oxide and sulfide containing a total of 8,099 short tons of antimony from domestic and foreign ores in 1949, a decrease of 43 percent from 1948. The Bureau of Mines is not at liberty to publish precise separate data on these three intermediate primary products. However,

[2] Traver, W. M., Investigation of Coyote Creek Antimony Deposits, Garfield County, Utah: Bureau of Mines Rept. of Investigations 4470, 1949. 18 pp.

ion of Antimony Peak, Kern County, Calif.: Bureau

about 60 percent of the output in 1949 was in the form of oxide, whereas over 50 percent of the output in 1948 was metal.

Antimonial lead produced as a byproduct by domestic primary lead refineries totaled 41,402 tons containing 3,385 tons of antimony in 1949, a decrease of 59 and 41 percent, respectively, from the 1948 output of 100,764 tons containing 5,760 tons of antimony. Mild winters in 1947 and 1948, which decreased demand for storage batteries, as well as general consumer resistance to high prices, were the chief factors causing the decrease. A detailed discussion of antimonial lead production is contained in the Lead chapter of this volume.

Secondary.—Antimony produced at secondary metal plants, including 1,775 tons recovered from scrap at primary lead refineries, was 18,061 short tons, a decrease of 16 percent from output in 1948. A detailed review is contained in the Secondary Metals—Nonferrous chapter of this volume.

Antimony metal, alloys, and compounds produced in the United States, 1940–44 (average) and 1945–49 in short tons

Year	Primary metal, oxide, and sulfide (antimony content)	Antimonial lead produced at primary lead refineries						Total secondary antimony (content of alloys)
		Gross weight	Antimony content					
			From domestic ores [1]	From foreign ores [2]	From scrap	Total

[1] Includes primary residues and small quantity of antimony ore.
[2] Includes foreign base bullion and small quantity of foreign antimony ore.
[3] Data not available.

CONSUMPTION AND USES

For the fourth consecutive year consumption of primary antimony decreased. Consumption in metallic products dropped 26 percent and in nonmetallic products, 24 percent in 1949 from that of 1948. The use of secondary material, chiefly in metallic products, decreased 16 percent.

Processing losses of primary antimony, in addition to quantities consumed as shown in the accompanying table, were reported by Office of Materials Distribution (OMD) and Office of Domestic Commerce, United States Department of Commerce (ODC), as 1,371 tons, 2,467 tons, 646 tons, 2,049 tons, and 1,657 tons, respectively, from 1944 through 1948, an average loss of 7.6 percent for the 5-year period. In 1949 processing losses were about 314 tons.

[2] Includes miscellaneous metallic products.
[3] Included with "Other." Bureau of Mines not at liberty to publish separate figures.
[4] Consumption April through December 1947; January through March included with "Other."

STOCKS

Stocks of antimony raw materials were reduced in virtually all phases of the industry. Mine stocks of properties operated in 1949 (data on stocks of nonoperative mines are not available) decreased 756 tons from January 1 to December 31, and other industry stocks decreased 2,590 tons. All stocks of antimony held by the Office of Metals Reserve (OMR) on December 31, 1948, were disposed of during 1949, chiefly by transfer to the National Stockpile. The Bureau of Mines is not at liberty to publish data on stocks in the National Stockpile.

[1] Data for 1948 compiled by Office of Domestic Commerce, U. S. Department of Commerce.

PRICES

The price of domestic antimony metal in bulk, f. o. b. Laredo, Tex., was quoted at 38.5 cents per pound from October 8, 1948, to October 7, 1949, then 32 cents per pound to the end of the year. For purposes of calculating the value of antimony, the 1949 average New York equivalent of the Laredo price published by American Metal Market is used in this chapter except for imports and exports. The New York price is about 1.78 cents a pound higher than the Laredo quotation, and the average quoted for 1949 was 38.73 cents. In 1948 the average New York price was 36.67 cents. The price for Chinese antimony per pound, min. 99 percent, in cases f. o. b. New York, duty paid, was considerably less than that for domestic metal most of the year. Opening quotations and changes published by E&MJ Metal and Mineral Markets, in cents per pound, follow: January 1, nominal; January 20, 38.5; March 10, 38–38.5; April 21, 38; May 5, 36–38; July 14, 34–36; July 21, 36–38; August 4, 34–36; August 18, 32–34; October 13, 27–28; and October 27, 26.

Year opening and changes in nominal quotations, according to E&MJ Metal and Mineral Markets, for antimony ore per unit (20 pounds) of antimony contained were as follows:

	50–55 percent	*58–60 percent*	*60–65 percent*
January 1	\$5. 00–\$5. 10	\$5. 10–\$5. 20	\$5. 20–\$5. 30
May 5	4. 80– 4. 90	4. 90– 5. 00	5. 00– 5. 10
July 21	4. 00– 4. 50	4. 40– 4. 50	4. 50– 4. 60
August 4	3. 80– 4. 10	4. 10– 4. 30	4. 30– 4. 40
September 15	3. 60– 3. 80	3. 90– 4. 00	4. 10– 4. 20
September 29	3. 60– 3. 80	3. 90– 4. 00	4. 00– 4. 10
October 13	3. 40– 3. 50	3. 50– 3. 60	3. 60– 3. 80
December 8	2. 80– 2. 90	2. 90– 3. 00	3. 00– 3. 20
December 15	2. 70– 2. 80	2. 80– 2. 90	2. 90– 3. 00

FOREIGN TRADE [3]

Imports.—General imports of antimony in antimony ore, metal, and needle or liquated antimony decreased 44, 42, and 85 percent, respectively, from those of 1948. The general decrease in imports was due chiefly to the small consumer demand. Imports of ore and concentrates came principally from Mexico, Bolivia, Peru, and Chile (material imported from Chile was probably mined in Bolivia or Peru). Imports of metal were chiefly from Mexico, Yugoslavia, Belgium-Luxembourg, and China. The needle antimony was from China. In addition to the imports for consumption shown in the accompanying table, 56 short tons (gross weight) of antimony oxide valued at \$27,290 were imported from the United Kingdom (11 tons) and Belgium (45 tons) in 1949.

[3] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Antimony imported for consumption in the United States, 1940–44 (average) and 1945–49

[1] Data include antimonyi mported for consumption, plus material entering the country under bond.
[2] Revised figure.
[3] Imports shown from Chile probably were mined in Bolivia or Peru and shipped from a port in Chile.

Exports.—Exports in 1949 (gross weight) of antimony ore and concentrates were 35 short tons valued at $10,984; metal and alloys, 450 tons valued at $337,177; and salts and compounds, 223 tons valued at $151,932. During 1948, exports (gross weight) included 69 short tons of antimony ore and concentrates valued at $29,727 and 258 tons of metal and alloys valued at $181,070. Data on exports of compounds were not available for 1946–48. Reexports of ore and concentrates in 1949 were 27 tons valued at $8,557. There were no transactions in metal and alloys. During 1948, reexports of foreign ore and concentrates were 204 short tons valued at $66,371 and of foreign metal and alloys 390 pounds valued at $105.

Foreign antimony (regulus or metal) exported from the United States, 1945–49

[U. S. Department of Commerce]

Year	Short tons	Value	Year	Short tons	Value
1945	463	$141,301	1948	(1)	$105
1946	139	43,197	1949	-------------	----------
1947	40	19,341			

[1] 390 pounds.

WORLD REVIEW

World production of antimony in recent years, insofar as data are available, is shown in the accompanying table. Decreases in output in 1949 of most of the countries supplying the United States can be attributed to lack of consumer demand in the United States. Exceptions are Yugoslavia, where an increase was reported, and China, where production was interrupted by war.

Canada.—Antimony output in 1949 was 50 percent less than in 1948. Imports of antimony regulus increased from 1,093,835 pounds in 1948 to 2,583,635 pounds in 1949. Most of the 1949 imports were from China, followed by the United States, Belgium, and the United Kingdom.

China.—Imports of antimony into Hong Kong in 1949 were 1,986 metric tons—1,535 from south China, 449 from north China, and 2 from Macao. Exports from Hong Kong during the year were 1,347 tons, Germany being shipped 608 tons, Canada 500, the U. S. S. R. 200, the United States 35, and Thailand and the Philippines the remainder. Hunan Province, in which lie China's principal antimony deposits, fell to the Chinese Communists in December 1949.

French Morocco.—A description of the antimony deposits in Morocco appeared in Echo des mines et de la métallurgie.[4]

Germany (Soviet Zone).—The Oberboehmsdorf mine, by a new process, produced the first antimony metal in the Soviet Zone in 1949. Antimony ore formerly was sent to Czechoslovakia for treatment.

Japan.—Nihon Seiko (Japan Concentrate) Co., owner of the Nakase mine, completed and began operation of an antimony smelter at Sekinoyamura, Hyogo Prefecture, in October 1948. The mine is said to contain 1,000,000 tons of probable ore averaging 30 grams of silver and 5 grams of gold per ton and 1 percent antimony. It was the only antimony producer in 1949.

[1] Approximate recoverable metal content of ore produced, exclusive of antimonial lead ores; 92 percent of reported gross content is used as basis for calculations in nearly every instance. U. S. S. R. and Yugoslavia produce antimony, but data on production are not available; an estimate for Yugoslavia is included in the total.
[2] Includes antimony content of antimonial lead.
[3] Excludes Soviet Zone, data for which are not available.
[4] Estimate.
[5] Data not available; estimate included in total.
[6] January to June, inclusive.
[7] Data represent Trianon Hungary after October 1944.
[8] Data represent area designated as Free China during the period of Japanese occupation.
[9] Fiscal year ended March 20 of year following that stated.
[10] Excluding New South Wales; data not available.
[11] Estimated by senior author of chapter.

Mexico.—The decline in production of antimony from 6,790 metric tons in 1948 to 5,293 tons in 1949 was due largely to curtailed output by the National Lead Co. because of the prevailing low consumer demand in the United States. Additional equipment installed at the Monterrey lead refinery of American Smelting & Refining Co. will increase its metallic antimony capacity to 250 tons a month, almost double the previous capacity. An antimony deposit is reported to have been located in the Sierra de Coronado Mountains in San Luis Potosi State, 7 miles from a railroad.

United Kingdom.—Imports of recoverable antimony in ores and concentrates declined 12 percent in 1949. Imports of antimony metal were negligible. Consumption of antimony metal and compounds also declined 12 percent, whereas scrap consumption was only 5 percent less and represented 44 percent of total consumption.

Arsenic

By Jack W. Clark

GENERAL SUMMARY

THE STRONG trend in consumer preference for organic insecticides over arsenicals continued unabated in 1949 and, coupled with more ready availability of the organics at reduced prices, brought the domestic white arsenic industry to a near-impasse. Producers of

Historical salient statistics for white arsenic in the United States, 1910–49, in short tons

[1] For years before 1910, see Mineral Resources of the United States, 1919, pt. 1, p. 19.
[2] Figures for 1943–45 reported by U. S. Department of Commerce; figures for all other years reported by producers to Bureau of Mines.
[3] Producers' shipments, plus imports minus exports.
[4] Refined white arsenic, carlots, as quoted by Oil, Paint and Drug Reporter.
[5] Data not available.
[6] Consumption based on allocation data of the War Production Board was 40,442 tons in 1941, 41,520 tons in 1942, 51,083 tons in 1943, and 43,509 tons in 1944.
[7] Excludes Government stocks as follows: 1942, 2,693 short tons; 1943, 1,018; 1944, 3,029; 1945, 1,987.
[8] Corrected figure.
[9] Conjectural.

arsenical insecticides ordinarily consume the bulk of the output of white arsenic. The seriousness of the situation was amply evidenced by markedly lowered apparent consumption and imports of white arsenic, both of which plunged to the lowest levels since 1922. No exports were reported by producers. Producers' stocks were the highest on record; and output of white arsenic reached the lowest point since 1933, with the exception of the strike-ridden year 1946.

DOMESTIC PRODUCTION

Crude and refined white arsenic was produced in 1949 by the Anaconda Copper Mining Co., at Anaconda, Mont. (copper smelter); United States Smelting, Refining & Mining Co., at Midvale, Utah (lead smelter); and American Smelting & Refining Co., in plants at Tacoma, Wash. (copper smelter), El Paso, Tex. (copper and lead smelter), and Murray, Utah (lead smelter). The Murray smelter was shut down on October 1, 1949, as a result of a long-continued shortage of ore and other economic factors. Arsenic metal was produced by Anaconda Copper Mining Co., 1949 output falling about 35 percent below 1948. Arsenical cobalt-nickel concentrates from Canada continued to be processed by Shepherd Chemical Co., Cincinnati, Ohio, for the preparation of sodium arsenite solution.

During 1949 Getchell Mine, Inc., operating in the Potosi district, Humboldt County, Nev., essentially completed construction of a new mill designed to treat 1,500 tons of arsenical gold ore per day. The arsenic is present in the minerals realgar, orpiment, and arsenopyrite. The realgar and orpiment will be removed by flotation and, being gold-free, will be stock-piled as such. It is estimated that daily production of realgar-orpiment concentrates will total 30 to 60 tons. Jardine Mining Co., Jardine, Mont., which had been mining high-arsenic gold-tungsten ores, suspended operations in August 1948.

Production and shipments of white arsenic by United States producers, 1940–44 (average), and 1945–49

Year	Crude			Refined			Total		
	Production (short tons) [1]	Shipments		Production (short tons)	Shipments		Production (short tons)	Shipments	
		Short tons	Value [2]		Short tons	Value [2]		Short tons	Value [2]
1940–44 (average)	25,638	26,015	$1,006,262	5,050	5,196	$245,240	30,688	31,211	$1,251,502
1945	21,358	22,180	1,041,614	2,991	2,630	155,447	24,349	24,810	1,197,061
1946	8,981	10,448	557,986	1,230	1,591	97,091	10,211	12,039	655,077

[1] Excludes crude consumed in making refined. Includes crude white arsenic equivalent of compounds made directly from ores, flue dust, and speiss as follows: 1945, 112 tons; 1946, 180; 1947, 97; 1948, 88; 1949, 26.
[2] Partly estimated.
[3] Revised figures.

CONSUMPTION AND USES

White arsenic is consumed principally in making calcium and lead arsenate. Most of the calcium salt is employed for controlling cotton insects, the lead compound being used largely by apple growers to combat codling moths. Production of both calcium and lead arsenate

is usually closely related to the anticipated near-term requirements of agricultural consumers.

Apparent consumption of white arsenic in 1949 dropped 39 percent below the previous year, despite the fact that cotton acreage was the highest since 1937, cotton insect infestation was of near-record proportions, and unusually wet weather necessitated repeated crop-dustings. More ready availability and lowered prices of preferred organic insecticides—chiefly benzene hexachloride, toxaphene, and chlordane—were the chief factors responsible for the accelerated trend away from arsenicals. DDT (dichloro-diphenyl-trichloroethane) continued to displace lead arsenate to a large extent in the apple industry, reportedly being lower in cost, more generally effective, and less of a problem in meeting tolerance requirements for spray residue. Additional production facilities for organic insecticides were completed in 1949 and still others were under construction.

Arsenic in various forms continues to be consumed in producing glass, wood preservatives, acid inhibitors, poisoned baits, and weed killers, sheep dip, alloys, and pharmaceuticals.

Production of arsenical insecticides and consumption of arsenical wood preservatives, in the United States, 1941–44 (average), and 1945–49

Year	Production of insecticides (short tons) [1]		Consumption of wood preservatives (pounds) [2]
	Lead arsenate (acid and basic)	Calcium arsenate (100 percent $Ca_3(AsO_4)_2$)	Wolman salts (25 percent sodium arsenate)
1941–44 (average)	37,694	32,046	1,128,854
1945	35,261	[3] 12,822	732,154
1946	28,334	17,696	1,669,889
1947	15,094	23,594	1,156,847
1948	[3] 12,316	[3] 13,618	1,286,302

[4] Preliminary figure.

STOCKS

Year-end producers' stocks of white arsenic for 1949 rose sharply for the third consecutive 12-month period, reaching 7,326 short tons, and were the highest since 1939, the first year for which the Bureau of Mines compiled such data.

PRICES

The carlot quotation for refined white arsenic held at 6 cents per pound for the first 9 months of 1949, dropping to 5¾ cents in the last quarter.

FOREIGN TRADE [1]

Imports.—Domestic receipts of white arsenic in 1949 plummeted for the second successive year and reached the lowest level recorded since 1922. Mexico accounted for 96 percent of the total in 1949.

[1] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

All 1949 imports of arsenic sulfide (value $5,594) originated in Belgium-Luxembourg; arsenical sheep dips ($9,809) came exclusively from the United Kingdom. Arsenic metal (total value $18,832) was received from Poland-Danzig (21,164 pounds), United Kingdom (13,405), and Sweden (10,800).

Arsenicals imported into and exported from the United States by classes, 1940–44 (average), and 1945–49, in pounds

[U. S. Department of Commerce]

Class	1940–44 (average)	1945	1946	1947	1948	1949
Imports for consumption:

[1] Corrected figure.

Exports.—Producers of white arsenic reported no foreign sales in 1949. Shipments of calcium arsenate to European countries eligible for aid from the Economic Cooperation Administration dropped noticeably below 1948 but were still significant; increased demand from the important Latin American market was a compensating factor, accounting for 68 percent of total exports. Colombia was the principal recipient. The lead arsenate export pattern, which had been distorted in 1948 by large ECA-financed shipments to the Orient, reverted to normal in 1949, almost 97 percent of all material exported being destined for Latin America, notably Brazil and Cuba.

TECHNOLOGY

A method was described for plant-scale production of crystalline and amorphous arsenic metal by thermal dissociation of arsenopyrite,[2] and commercial processes were reviewed for separating arsenic from antimony [3] by flotation, caustic soda interaction, and roasting. The problems involved in the treatment of arsenical gold ores continued to receive attention.[4]

WORLD REVIEW

Australia.—About 61,000 tons of white arsenic were produced in Australia to the end of 1948; of this total the Wiluna gold mine in Western Australia accounted for 39,000 tons in the period 1931–47. As of September 1, 1948, Victor Leggo Mining Co. Pty., Ltd., Bendigo, Victoria, set the purchase price of arsenic contained in gold ores at 4s. 5d. per unit.[5]

Belgium.—Various arsenic products are made by Société Générale Métallurgique de Hoboken at plants near Antwerp, Herenthals, and at Reppel, near Bree (white arsenic, yellow and red sulfides, insecticides and other compounds); by Société des Mines et Fonderies de Zinc de la Vieille-Montagne, Liège (arsenicals); and by Belgochimie S. A., Ghent (arsenical copper and lead and calcium arsenate).

France.—Société Minère et Métallurgique de Penarroya produces arsenic compounds as byproducts of smelting lead, zinc, and silver ores at plants located at Noyelles-Godault and Estaque.

Greece.—White arsenic is recovered at the lead-silver smelter of Compagnie Française des Mines du Laurium, Ergosteria.

Hungary.—Sizable bodies of enargite ore have been reported discovered at the Recsk gold-copper mine.[6] It is stated that the property which shut down in 1948 will reopen and that arsenic will be produced in quantity.

Mexico.—Byproduct white arsenic is recovered by Compañia Metalurgica Peñoles, S. A. (subsidiary of American Metal Co.), at its Torreon, Coahuila, lead smelter. During the year additional baghouse facilities were placed in operation. The copper smelter of American Smelting & Refining Co., San Luis Potosi, S. L. P., also produced white arsenic.

Tunisia.—Arsenical lead and white arsenic are byproducts of lead smelting at the Djebel-Hallouf plant of Société Anonyme Française du Djebel-Hallouf. Ore is obtained from the mine at Souk-El-Khemis.

United Kingdom.—Arsenic metal is produced by Metallo Chemical Refining Co., Ltd., and Imperial Smelting Corp., Ltd., London. The latter company also produces arsenic alloys. Arsenical copper is made by British Copper Refiners, Ltd., Prescot, Lancashire.

Asbestos

By G. W. Josephson and F. M. Barsigian

GENERAL SUMMARY

EARLY in 1949 there were some indications that supply and demand for asbestos were coming into balance. This situation, however, was changed by a long strike in the Canadian asbestos field. During the strike stocks in consumers' hands approached exhaustion, and after the settlement asbestos was generally in short supply as consumers attempted to catch up on backlog and accumulate working stocks.

In the United States a new asbestos production record was established, but only a small part (8 percent) of our total requirements were supplied from domestic mines.

Our domestic production comes principally from a single chrysotile mine in Vermont; relatively small quantities (including some chrysotile of spinning grade) were mined in Arizona. There was also a small output of amphibole asbestos in a number of other States.

Although demand in the United States was at a high level, imports from foreign sources were lower than in the record year 1948 because of the strike in Canada. Small quantities of chrysotile were imported from Southern Rhodesia and Russia. South Africa supplied all of the amosite and nearly all of the crocidolite consumed in the United States. Interest is developing in Bolivian crocidolite, which has been found to be a good raw material for filtering uses.

Industrial demand for asbestos absorbed most of the available supply, and consequently stockpiling was difficult, but some progress was made in substitution programs. After a price increase at the first of the year, prices of raw asbestos remained comparatively stable during 1949.

Salient statistics of the asbestos industry in the United States, 1948–49

	1948		1949	
	Short tons	Value	Short tons	Value
Domestic asbestos—				
Produced	37,237	(1)	42,918	(1)

[1] Figure not available.
[2] Quantity sold or used by producers, plus imports, minus exports.

PRODUCTION

Production of asbestos in the United States reached a record of 42,918 short tons in 1949, 15 percent more than in 1948. Chrysotile was produced in Vermont and Arizona, and some development work was reported in California. Amphibole output was reported from California, Georgia, and Oregon.

Asbestos sold or used by producers in the United States, 1945–49, by varieties

Year	Chrysotile		Amphibole		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1945	11,986	$442,056	240	$3,989	12,226	$446,045
1946	13,645	499,260	430	5,504	14,075	504,764

1948	(1)	(1)	(1)	(1)	37,092	1,806,261
1949	(1)	(1)	(1)	(1)	43,387	2,614,416

[1] Bureau of Mines not at liberty to publish figure separately.

Alaska.—There was no production of asbestos in 1949 from the Alaskan deposits in the Kobuk River district. A comprehensive report on these deposits was issued by the Bureau of Mines.[1]

Arizona.—In 1949 chrysotile production in Arizona was somewhat lower than in the previous year, but some high-quality material suitable for the National Stock Pile was recovered. The following firms and individuals were active: Apache Asbestos Mines, Inc., 3402 North Central Ave., Phoenix; Arthur Enders, P. O. Box 362, Globe; Charles Ireland, P. O. Box 374, Globe; Kyle Asbestos Mines of Arizona, P. O. Box 302, Globe; Phillips Asbestos Mines, P. O. Box 71, Globe; and R. G. Robertson (Bear Canyon mine).

California.—In Shasta County production of tremolite in the Sylvester mine was reported by the Powhatan Mining Co., Woodlawn, Baltimore, Md. Homer E. Fenn and associates did some development work at the Stock Asbestos mine. Huntley Industrial Minerals, Inc., P. O. Box 305, Bishop, Calif., has reported that it expects to start production of asbestos in Inyo County about May 1, 1950. The Blas Asbestos Corp., La Moine, Calif., continued development of its chrysotile asbestos deposit and mill in Shasta County but was not in commercial production.

Georgia.—Powhatan Mining Co. produced anthophyllite in Rabun County, Ga., near Dillard. Industrial Minerals Corp. reported development work on tremolite in Rabun County.

Montana.—Considerable development work was done by Interstate Products Co., Inc. (126 Ave. C, Billings, Mont.), in Gallatin County. Several deposits of amphibole asbestos have been opened.

North Carolina.—There was no commercial production reported in North Carolina in 1949, but Industrial Minerals Corp., Asheville, continued development work on amphibole deposits in Macon and Yancey Counties.

Oregon.—Philip S. Hoyt, P. O. Box 83, Aguila, Ariz., reported some production in Oregon of asbestos suitable for use as filter fiber.

[1] Heide, H. E., Wright, W. S., and Rutledge, F. A., Investigations of the Kobuk River Asbestos Deposits, Kobuk District, Northwestern Alaska: Bureau of Mines Rept. of Investigations 4414, 1949, 25 pp.

Vermont.—The Vermont Asbestos Mines Division of the Ruberoid Co., 500 Fifth Ave., New York 18, N. Y., the largest producer of asbestos in the United States, increased the output of its mine and placed a new fiber-processing mill in operation at Lowell, Vt., in 1949. The company consumes this chrysotile asbestos in the manufacture of asbestos products.

CONSUMPTION AND USES

As shown in the accompanying table, the apparent consumption of raw asbestos in the United States was substantially lower in 1949 than it was in 1948. There were industry reports that demands for various asbestos products were declining, particularly in the early part of the year, but a substantial part of the drop in total consumption can be attributed to the shortage of asbestos caused by the Canadian strike. Whereas there were declines in demand for textiles and some additional asbestos products, sales of others, such as asbestos-cement products, were sustained by the high level of activity maintained by the building industry. The relationships between the consumption of asbestos and activity in its major markets—construction and industry in general—during the past 30 years, are shown graphically in figure 1.

A table showing output of asbestos products in the United States in 1939 and 1947, compiled from the Census of Manufacturers, was published in Minerals Yearbook, 1948, page 146.

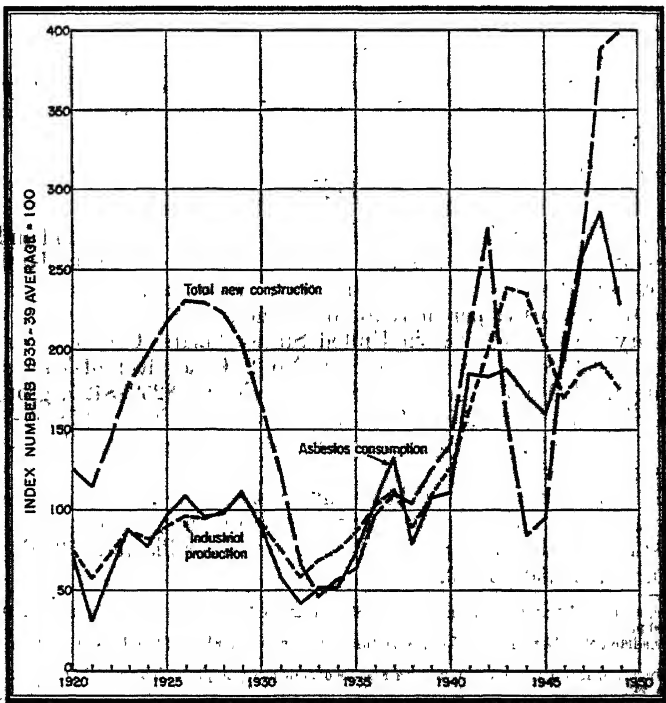

FIGURE 1.—Consumption of asbestos compared with total new construction and industrial production, 1920–49. Statistics on value of construction from Bureau of Foreign and Domestic Commerce and on industrial production from Federal Reserve Board.

Apparent consumption of raw asbestos in the United States, 1945–49

Year	Short tons	Value	Year	Short tons	Value
1945	378,030	$15,926,622	1948	678,443	$38,607,094
1946	459,752	17,840,775	1949	541,069	32,935,295
1947	616,787	30,423,663			

In general, the demand for raw asbestos was very active during 1949, both in the United States and elsewhere. New uses continued to appear, and a number of consumers continued their expansion programs, although probably not at the rate that would have been attained if an ample supply of asbestos had been available. The need for asbestos has become well known throughout the world, and consequently exploration projects have been very active in many areas. New mines have not yet made very large contributions to current supply, but several show promise.

The shortages of the higher grades of asbestos obtained from Africa continued throughout 1949, and consequently greater emphasis was put on beneficiation and substitution programs.

Several revealing publications on asbestos uses were issued in 1949. These included a manual on 85-percent-magnesia insulation [2] and a pamphlet on the properties and uses of shorts and floats.[3] A new type of high-quality asphalt roofing having a surface coating of asbestos fibers was introduced. This shingle is said to have exceptionally high fire resistance.[4]

A description of the use of asbestos in brake linings was published.[5] Asbestos is a principal constituent of a new type of high-efficiency air filter. It is reported that Bolivian crocidolite, which has had comparatively little market in the past, is particularly suited to that application.

PRICES

Trade-journal price quotations for all grades of crude and milled asbestos from both Canada and Vermont were increased in January and remained constant for the entire year. As quoted in the magazine, Asbestos, the prices per short ton of Canadian fiber, f. o. b. mines, in January were as follows, in United States dollars: Group 1 (Crude No. 1), $960–$1,050; group 2 (Crude No. 2, Crude Run-of-Mine, and Sundry), $400–$550; group 3 (Spinning Fiber), $232–$425; group 4 (Shingle Fiber), $95.50–$141; group 5 (Paper Fiber), $78.50–$88; group 6 (Waste, Stucco, or Plaster), $58; and group 7 (Refuse or Shorts), $28–$52.

The prices of Vermont asbestos in short tons f. o. b. Hyde Park or Morrisville, Vt., quoted in January 1949, were: Shingle Fiber, $111.50–$124; Paper Fiber, $79–$96.50; Waste, Stucco, or Plaster, $59; Refuse or Shorts, $28.50–$52.50.

FOREIGN TRADE [6]

As the United States is the principal consumer of asbestos and produces only a small percentage (8 percent in 1949) of its requirements, large tonnages are imported. In 1949 imports of unmanufactured asbestos were 20 percent lower than in 1948. Of the total, 91 percent came from Canada, 4 from Southern Rhodesia, and 4 from the Union of South Africa. Smaller quantities were received from Russia and other countries.

Asbestos imported for consumption in the United States, and asbestos and asbestos products exported from the United States, 1945–49

[U. S. Department of Commerce]

Year	Asbestos (unmanufactured)				Manufactured asbestos products-exports (value)
	Imports		Exports		
	Short tons	Value	Short tons	Value	
1945	374,354	$16,317,752	8,550	$837,175	$7,264,288

[1] Less than 1 ton.
[2] Revised figure.
[3] Includes the following crude credited to Mozambique by the U. S. Department of Commerce: 1948—1,055 tons, $106,431; 1949—3,848 tons, $269,941.

[6] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

As compared with imports, United States exports of unmanufactured asbestos are comparatively small. However, in 1949 exports were almost three times as great as in 1948. The value of manufactured asbestos products shipped out of the country is substantial.

Manufactured asbestos products exported from the United States, 1948–49, by kinds

[U. S. Department of Commerce]

Products	1948		1949

[1] Classified by the U. S. Department of Commerce: 1948—Paper, millboard, and rollboard, 1,639 tons, $308,384; asbestos roofing, 210,238 squares, $1,392,071; other asbestos manufactures, except roofing, $1,151,088; 1949—Asbestos construction materials, 21,362 tons, $2,418,172; other asbestos manufactures, except roofing, $473,219.
[2] Quantity not recorded.

New classifications available on exports of unmanufactured asbestos in 1949 provided the following additional data: Crude and Spinning Fibers, 5,885 long tons (6,591 short tons) valued at $1,741,984; nonspinning, 4,947 long tons (5,541 short tons) valued at $1,327,876; Waste and Refuse, 4,901 long tons (5,489 short tons) valued at $548,843.

TECHNOLOGY

The industry is making real progress in the search for methods of removing magnetite from Canadian chrysotile to make it acceptable for the highest specification cable wrapping applications. The Johns-Manville Co. is producing Quinterra paper for this purpose, and the Raybestos Manhattan Co. has another wet-process beneficiation pilot plant in operation.

Much work has been done in recent years on crystal-growth problems, and the body of information is reaching a point where technologists feel that there is prospect of discovering methods of synthesizing asbestos in quantity. It is anticipated that these products may not have exactly the same chemical compositions as the natural forms of asbestos but will have similar physical properties. Such investigations are being continued both in the laboratories of private firms and the Government. A project on asbestos synthesis was established at the Norris, Tenn., station of the Bureau of Mines in 1949.

A paper on filterability of asbestos fibers used in wet process [7] and a review of current methods of mining and milling asbestos [8] were published.

WORLD REVIEW

Although official statistics are too incomplete to make a highly accurate estimate possible at this time, it is believed that world output of asbestos in 1949 was of the order of 100,000 tons lower than in 1948, owing to interruption of production in Canada, which was only partly compensated by moderate increases in other countries.

World production of asbestos by countries, 1944–49, in metric tons [1]

[9] Less than 1 ton.

CANADA

In 1949 asbestos production in Canada dropped to 574,906 short tons valued at $39,746,072. This 20-percent decrease in tonnage from the output record established in 1948 was due to the strike in the Thetford mines district that lasted from February 13 to July 5.[9]

[7] Badollet, M. S., Filterability of Asbestos Fibers Used in Wet Processes: Canadian Min. and Met. Bull., vol. 42, No. 451, November 1949, pp. 594–598.
[8] Messel, M. J., Recent Trends in Asbestos Mining and Milling Practice: Min. Eng., vol. 1, No. 2, February 1949, pp. 52–55.
[9] Engineering and Mining Journal, Quebec: Vol. 150, No. 8, August 1949, p. 122.

Partly as a result of the strike and partly because of the high world-wide demand for asbestos, exploration and development activities were at a high level in Canada during 1949. Outstanding was the announcement by the Johns-Manville Co. of the discovery and projected development of a rich asbestos deposit 9 miles east of Matheson, Ontario, in the Larder Lake district, Munro Township. A new mill having an hourly capacity of 50 tons of mill rock is to be built, and mine production was expected in mid-1950.[10]

Sales of asbestos in Canada, 1948–49, by grades

[Quebec Department of Mines]

1 Data not available.

Prospecting and development work on many other properties were also reported. It was said that a claim in Deloro Township, Porcupine area, northern Ontario, which had been idle since World War I, is to be opened by the Teegana Mines, Ltd.[11] Calabogie Asbestos Mining Co., Ltd., planned development of a 200-acre property in Blythfield Township, Renfrew County, Ontario.[12] Three groups of claims in Joannes, Dasserat, and Rigaud-Vadreuil Townships, Quebec, were to be extensively explored by Arnora Gold Mines, Ltd.[13] The United Asbestos Corp. announced that it had obtained surface rights on the shores of Black Lake, under which its deposit lies, suitable for a mill site.[14] The Acme Asbestos Co., Ltd., Vancouver, B. C., optioned a group of chrysotile asbestos claims on Sproat Mountain, 4 miles north of Arrowhead, B. C. The asbestos is said to be of good quality, but the extent of the deposit is not known.[15] Bar-Lan Gold Mines has commenced surface work on its newly acquired asbestos property in Coleraine Township, Quebec.[16]

AFRICA

Southern Rhodesia.—As shown in the accompanying table, chrysotile asbestos production in Southern Rhodesia increased considerably in 1949. The bulk of this output comes from mines operated by Rhodesian & General Asbestos Corp., a subsidiary of Turner & Newall,

10 Johns-Manville Stockholders' News, J-M Discovers New Asbestos Deposits: July 1949.

Ltd. They include the Nil Desperandum, Sphinx, Birthday, 170, and 177 lodes in the Shabani district; the King and Gath mines in the Mashaba district; and the Croft mine in the Filabusi district. In the past few years many asbestos properties in Southern Rhodesia have been opened, but they are contributing a relatively small tonnage to the total. Shipments were started from the new Vanguard Asbestos Mines operation at Belingwe.[17]

Asbestos produced in Southern Rhodesia, 1944–49

Year	Short tons	Value	Year	Short tons	Value
1944	58,293	£1,674,467	1947	54,094	£1,738,484
1945	[1] 56,293	1,788,386	1948	68,897	2,604,623
1946	55,872	1,676,503	1949	79,638	3,986,703

[1] Revised figure.

Swaziland.—The increase in chrysotile production at the Havelock mine in Swaziland was not very great tonnagewise, but it was enough to raise the total to a new record of 30,814 metric tons in 1949.

Union of South Africa.—Results of the amosite expansion program are beginning to show in the production figures, which reached a record total of 31,392 short tons in 1949. As shown in the accompanying table, there was also an increase in output of Transvaal Blue. A trade-journal report in October indicated that the number of asbestos mills in the Transvaal had increased since July 1948 from 6 to 27, with several more in construction.[18]

Expansion of the Benoni asbestos products factory operated by Cape Asbestos Insulation (Pty.) is expected to double its current rate of asbestos consumption, 300 tons per month.[19]

Asbestos produced in and exported from the Union of South Africa, 1945–49[1]

Year	Production (short tons)			Exports	
	Transvaal	Cape Province	Total	Short tons	Value
1945	20,016	8,200	28,216	22,005	£591,124
1946	12,636	7,589	20,225	21,481	557,008

[2] January to September, inclusive.

OTHER COUNTRIES

Inasmuch as such information is scattered and difficult to obtain, a series of short articles published in the magazine Asbestos, outlining asbestos production and occurrences in a number of countries, is of interest. In 1949 information was published on Albania, Australia, Bulgaria, China, Cyprus, Czechoslovakia, Egypt, Eritrea, Finland, France, French Morocco, Germany, Greece, India, Indochina, Italy, Japan, and South America.

Australia.—A small tonnage of asbestos was produced in Australia in 1949. The bulk was blue asbestos produced in Western Australia. It was reported that surveys made by the State Mines Department were expected to lead to the opening of new white asbestos deposits in Tasmania.[20]

Austria.—A discovery of a deposit of asbestos was reported from Rottenmann, Styria.[21]

Bolivia.—Output of Bolivian crocidolite was small in 1949, but it may increase in future if the use of dry filters, for which it appears to be particularly suitable, reaches a substantial magnitude.

Colombia.—Exploration of two deposits, near the towns of Yarumal and Antioquia, in Antioquia, was reported.[22]

India.—Deposits of good asbestos are reported to be mined by primitive methods and shipped in raw form from Brahmanapalli, Cuddapah, and Lopatantulu districts.[23]

Italy.—Italian asbestos production is small but a record rate was attained.[24]

Venezuela.—Asbestos production in Venezuela continued at a low rate. The only producer, C. A. Minas de Amianto de Tinaquillo, which operates the El Tigre mine near Tinaquillo, is attempting to expand.

Asphalt and Related Bitumens

By A. H. Redfield and Sarah J. Spencer

GENERAL SUMMARY

DOMESTIC demand[1] for petroleum asphalt was nearly 1 percent lower in 1949 than in 1948, but export demand was 13 percent lower. As export demand was only 2½ percent of the total demand, the total demand decreased a little more than 1 percent from 1948 to 1949. In numerical terms, a decrease of 87,400 tons in domestic demand, coupled with a decrease of 35,500 tons in export demand, was met by a decrease of 529,500 tons in refinery production and a decrease of 70,700 tons in imports of petroleum and lake asphalt. As a result, stocks held at the refineries were lowered by 134,400 tons during 1949, compared with additions of 342,900 tons to stocks during 1948.

NATIVE ASPHALT AND BITUMENS

Bituminous Rock.—Sales of bituminous rock by producers in the United States increased from 1,084,004 short tons valued at $3,634,917 in 1948 to 1,150,931 tons valued at $4,264,989 in 1949. Bituminous limestone amounted to 904,183 tons valued at $2,292,873 in 1948 and 920,874 tons valued at $2,536,912 in 1949. Bituminous sandstone totaled 179,821 tons valued at $1,342,044 in 1948 and 230,057 tons valued at $1,728,077 in 1949. One company in Texas, one in Kentucky, one in Oklahoma, and one in Utah were responsible for the general increase. Sales values per ton at the mine were generally higher in 1949 than in 1948.

Gilsonite.—Sales of gilsonite by producers in northeastern Utah decreased from 52,122 short tons valued at $1,390,713 in 1948 to 51,462 tons valued at $1,303,584 in 1949. The average sales value per ton at the mine or railhead decreased from $26.68 in 1948 to $25.33 in 1949.

MANUFACTURED OR PETROLEUM ASPHALT

Production.—Petroleum refineries in the United States produced 8,910,300 short tons of asphalt in 1949, a decrease of 6 percent from the 9,439,800 tons produced in 1948. The decreases were greatest in the East Coast, Indiana-Illinois-Kentucky, etc., and Louisiana Gulf Coast districts. On the other hand, refineries in California and Texas increased their asphalt output from 1948 to 1949.

Stocks.—Stocks of asphalt held at refineries decreased 13 percent from 1,028,600 short tons on December 31, 1948, to 894,200 tons on December 31, 1949. In some of the smaller producing districts, inventories were decreased as much as one-third. In contrast, California refineries increased their stocks 30 percent during the year and refineries of Arkansas and Inland Louisiana 17 percent.

[1] The term "domestic demand" as used in this chapter means apparent consumption, that is, production plus net imports and changes in refiners' stocks.

Production, receipts, stocks, consumption, transfers, losses, exports, and domestic sales of asphalt (exclusive of road oil) at petroleum refineries in the United States in 1949, by districts, in short tons

[1] Receipts from interindustry refinery transfers, addition of other petroleum products blended to make cut-back asphalts, imports, and transfers from stocks formerly not classified as asphalt.

Sales.—Sales of petroleum asphalt to domestic consumers decreased 3 percent in quantity for 1948 to 1949 and, because of lower prices, 9 percent in value. The average sales value per short ton decreased from $19.48 in 1948 to $18.21 in 1949. The greatest decreases in tonnage sold were in the East Coast and Louisiana Gulf Coast districts. In contrast to the general trend, Texas Gulf Coast refineries increased their tonnage of sales 48 percent from 1948 to 1949, Appalachian refineries 27 percent, and refineries of Oklahoma-Kansas-Missouri 13 percent. California asphalt sales were slightly larger in 1949 than in 1948.

Of the total sold, 23 percent was manufactured from foreign petroleum (imported chiefly from Venezuela, Colombia, and Mexico) in 1949, compared with 26 percent in 1948. Although runs of foreign crude to stills increased 26 percent from 1948 to 1949, sales of petroleum asphalt from this source decreased 13 percent. Of the foreign crude processed, 10 percent was converted to asphalt in 1948 and 7 percent in 1949. Ninety-nine percent of the asphalt made from foreign crude in 1948 and all of it in 1949 was manufactured in east coast refineries.

Highway and street construction and airport-runway surfacing (in the form of paving asphalt, paving flux, cutback asphalts, and asphalt emulsions) used 67 percent of the total asphalt sold to domestic consumers by petroleum refineries in 1948 and 70 percent in 1949. Sales of all grades of asphalt devoted wholly or principally to street and road construction increased 2 percent in 1949 over 1948.

Sales of emulsified asphalts were slightly lower in 1949 than in 1948. Petroleum refineries sold 124,760 short tons (29,395,889 gallons) valued at $2,976,116 in 1948 and 74,151 tons (17,469,975 gallons) valued at $1,495,574 in 1949. In addition, 102,815,746 gallons valued at $11,009,785 in 1948 and 113,199,203 gallons valued at $13,482,130 in 1949 were sold by secondary producers that purchased asphalt from petroleum refineries and manufactured it into emulsions. Accordingly, total known sales of emulsified asphalts and fluxes decreased 1 percent in quantity—from 132,211,635 gallons (561,137 tons) in 1948 to 130,669,178 gallons (554,623 tons) in 1949—but increased 7 percent in value—from $13,985,901 in 1948 to $14,977,704 in 1949.

Roofing manufacture made the second-largest demand for asphalt, absorbing 28 percent of the total sales of asphalt to domestic consumers in 1948 and 26 percent in 1949. Although sales of prepared roofing and asphalt siding reported to the Bureau of the Census declined 13 percent—from 63,219,000 squares in 1948 to 54,856,000 squares in 1949—and of saturated felt 7 percent—from 538,042 short tons in 1948 to 500,688 tons in 1949—domestic sales of roofing asphalt and roofing flux combined decreased 10 percent—from 2,611,092 short tons in 1948 to 2,351,471 tons in 1949. These figures do not include roofing asphalt and flux consumed by the refining companies in factories making prepared roofing and siding and saturated felts, owned by themselves or by affiliated companies.

APPARENT CONSUMPTION

For the first time since 1942, the apparent consumption of asphalt declined. The apparent average monthly domestic consumption of petroleum asphalt (including small quantities of lake asphalt and grahamite) decreased 1 percent—from 795,641 (revised figure) short tons in 1948 to 752,362 tons in 1949. Total apparent consumption was 9,115,697 tons in 1948 and 9,028,348 tons in 1949.

DISTRIBUTION BY RAIL

Although the apparent domestic consumption of petroleum asphalt declined only 1 percent from 1948 to 1949, the tonnage of asphalt terminated by Class I railroads in the United States decreased 17 percent—from 6,764,934 short tons in 1948 to 5,584,389 tons in 1949, according to the Interstate Commerce Commission. It may be noted, however, that railroad terminations of asphalt were equivalent to only 74 percent of the total apparent consumption of asphalt in the United States in 1948 and 62 percent in 1949 and that considerable quantities of asphalt were delivered to consumers by water, minor railroads, and motor trucks. Accordingly, the figures in the accompanying table do not present a complete picture of the consumption of asphalt by States.

Of the total deliveries by rail, 56 percent in 1948 and 52 percent in 1949 were set down in the populous area north of the Ohio and Potomac Rivers and east of the Mississippi River, although this area comprises only 14 percent of the area of continental United States. In this area terminations of asphalt were 23 percent lower in 1949 than in 1948. In the States south of the Potomac and Ohio and east of the Mississippi, deliveries of asphalt were 16 percent less in 1949 than in

1948. Between the Mississippi River and the Rocky Mountains, railroad terminations of asphalt were 2 percent less in 1949 than in 1948; the largest decreases were in Texas and Missouri.

Increased deliveries of asphalt in Minnesota, Louisiana, Oklahoma, and North Dakota contrasted with the general regional decline in asphalt terminations. In the Rocky Mountain States receipts of asphalt by rail were 14 percent lower in 1949 than in 1948. In the three Pacific States rail deliveries of asphalt were 16 percent lower in 1949 than in 1948.

Asphalt (natural, byproduct, and petroleum) terminated by class I railroads in the United States, 1948–49, by States, in short tons

FOREIGN TRADE [2]

Imports.—Imports of natural asphalt and bitumen into the United States totaled 4,857 short tons valued at $167,264 (revised figures) in 1948 and 4,109 tons valued at $87,693 in 1949. Imports of lake asphalt from Trinidad decreased from 4,667 tons valued at $97,444 in 1948 to 4,104 tons valued at $73,715 in 1949. Imports of grahamite from

[2] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Cuba decreased from 76 tons valued at $2,297 in 1948 to 73 tons valued at $2,294 in 1949.

Imports of solid petroleum asphalt decreased from 249,008 short tons valued at $1,912,522 (revised figures) in 1948 to 194,911 tons valued at $2,351,632 in 1949. Except for 21 tons valued at $827, which were imported from Canada in 1948, all of these imports came from the Netherlands Antilles.

In addition, the United States received 191,880 barrels (34,887 short tons) of liquid petroleum asphalt valued at $506,930 in 1948 and 104,808 barrels (19,056 tons) valued at $263,321 in 1949. All of the 1948 imports and most of the 1949 imports came from the Netherlands Antilles; Mexico, however, contributed 491 barrels (89 tons) valued at $11,934 in 1949.

Exports.—The tonnage of natural asphalt, unmanufactured, exported from the United States increased from 13,682 short tons valued at $559,462 in 1948 to 16,672 tons valued at $823,143 in 1949. Of the 1949 exports, 66 percent went to Europe, notably to the United Kingdom, France, Germany, Italy, Denmark, Belgium, Sweden, and Switzerland. Canada received 15 percent of the total and Mexico 4 percent.

Exports of petroleum asphalt from the United States in 1949 declined from 269,958 short tons valued at $8,984,509 in 1948. Asia contrasted with the other continents; it took 56 percent of the total exports in 1949 compared with 40 percent in 1948. Europe, which received 33 percent of the total in 1948, accounted for only 17 percent of the whole in 1949.

Smaller exports to Europe were the principal factor in the general decline. The most conspicuous decreases were in shipments to Greece, Portugal, and Spain. Of the major European countries, only Austria and Germany received more asphalt from the United States in 1949 than in 1948.

Eastern and southeastern Asia received the greater part of the asphalt exports to Asia in 1949. The greatest increases were in shipments to Japan, French Indochina, and Indonesia; less was received by Korea.

Asphalt exports to Canada and Mexico, chief customers in North America, were lower in 1949 than in 1948. In spite of decreased shipments to Uruguay, more asphalt was shipped to South America in 1949 than in 1948.

Less asphalt was shipped to Australia and New Zealand in 1949 than in 1948.

Petroleum asphalt exported from the United States, 1947–49, by countries of destination

[1] Data shown are for "petroleum asphalt, unmanufactured." In addition, exports of "petroleum asphalt manufactures" were valued at $321,252 (quantity not available); not separately classified in earlier years.

ROAD OIL

Sales of road oil by petroleum refineries in the United States increased 11 percent in quantity—from 6,115,000 barrels in 1948 to 6,768,000 barrels in 1949—but, because of lower prices declined 2 percent in value—from $17,870,000 in 1948 to $17,485,000 in 1949. The increase in quantity was due principally to greater sales in California and in the Oklahoma-Kansas-Missouri district. Four refining districts—Indiana-Illinois-Kentucky, etc., Oklahoma-Kansas-Missouri, Rocky Mountains, and California—together made 95 percent of all the road-oil sales in 1948 and 97 percent in 1949.

Of the total sales of road oil to domestic consumers, 186,489 barrels valued at $698,172 in 1948 and 97,207 barrels valued at $397,074 in 1949 were made from foreign petroleum, imported chiefly from Venezuela, Colombia, and Mexico.

Production, receipts, stocks, consumption, transfers, losses, exports, and domestic sales of road oil in the United States in 1949, by districts, in thousands of barrels

Barite

By Joseph C. Arundale and F. M. Barsigian

GENERAL SUMMARY

DOMESTIC production and consumption of barite declined in 1949. Arkansas remained the leading producer with almost half of the total—nearly twice that of the next State, Missouri. New production was reported from New Mexico and South Carolina. Well drilling again took the major portion of the barite consumed. There was a sharp decrease in the tonnage consumed in lithopone. Trade-journal price quotations remained generally constant. Crude barite was imported from Canada, Yugoslavia, Italy, and Mexico, but total tonnage was the lowest in several years. The operations of Canadian Industrial Minerals, Ltd., near Walton, Nova Scotia, were discontinued temporarily in December. A large new deposit of barite was discovered in the Republic of the Philippines.

Salient statistics of the barite and barium-chemical industries in the United States, 1945–49

	1945	1946	1947	1948	1949
Barite:					
Primary:					
Produced .... short tons	692,330	725,223	884,219	777,841	731,308
Sold or used by producers:					
Short tons	696,062	724,362	834,082	799,848	717,313
Value	$5,348,652	$5,242,755	$6,171,342	$6,693,413	$5,642,226

Value	$382,611	$274,267	$378,294	$443,515	$192,567
Consumption .... short tons	720,903	722,073	835,818	894,309	719,543
Ground and crushed sold by producers:					
Short tons	468,939	455,240	549,965	631,424	554,028
Value	$7,519,759	$7,208,193	$8,979,400	$11,195,365	$10,156,590
Barium chemicals sold by producers:					
Short tons	68,084	80,871	72,919	71,717	56,792
Value	$6,493,448	$7,003,756	$7,035,104	$7,028,058	$5,646,403
Lithopone sold or used by producers:					
Short tons	136,161	147,001	165,024	140,033	78,335
Value	$10,645,316	$11,840,596	$17,382,592	$16,135,976	$8,977,178

A petition was made to the Interstate Commerce Commission for reopening hearings on rail rates on barite.

Hearings were held simultaneously by the Tariff Commission and the Committee for Reciprocity Information to receive industry views on commodities to be included in negotiations at the trade agreements conferences. At these hearings, industry representatives testified in opposition to further tariff reductions on ground barite.[1]

A general report was published describing the occurrences of barite, mining, prospecting, marketing methods, and uses.[2]

DOMESTIC PRODUCTION

The 731,308 short tons of primary barite[3] reported by domestic producers in 1949 was the third greatest annual output on record, being surpassed only in 1947 and 1948.

Arkansas, the leading State, produced almost half of the United States total and nearly twice as much as the second State, Missouri. Georgia and Tennessee production continued to decrease rapidly. New production was reported from New Mexico and South Carolina.

Domestic barite sold or used by producers in the United States, 1947–49, by States

State	1947		1948		1949	
	Short tons	Value	Short tons	Value	Short tons	Value
Arkansas[1]	376,017	$2,390,643	362,470	$2,899,760	363,382	$2,907,056
Georgia	61,202	639,865	62,781	654,959	50,267	465,325
Missouri	291,619	2,405,249	278,071	2,413,802	186,891	1,497,985
Nevada	37,388	261,168	(2)	(2)	70,576	416,416
Tennessee	31,476	285,853	25,818	275,242	13,376	137,120
Other States[3]	36,380	188,564	70,708	449,650	32,821	218,324
Total	834,082	6,171,342	799,848	6,693,413	717,313	5,642,226

[1] Value estimated.

Ground (and crushed) barite produced and sold by producers in the United States, 1945–49

Year	Plants	Production (short tons)	Sales	
			Short tons	Value
1945	20	473,749	468,939	$7,519,759
1946	23	456,327	456,246	7,208,193
1947	23	552,227	549,965	8,979,400
1948	23	630,808	631,424	11,196,365
1949	24	561,258	554,028	10,156,590

Arizona.—The Arizona Barite Co. continued to operate its mine and mill near Mesa, producing ground barite for the well-drilling trade.

Arkansas.—The two firms in Arkansas—Magnet Cove Barium Corp. and Baroid Sales Division of National Lead Co.—produced ground barite at their mines and plants near Malvern for use in well drilling. Near the end of 1949 it was announced that Dresser Industries, Inc., Cleveland, Ohio, would acquire the common stock of Magnet Cove Barium Corp., and continue the production of well-drilling compounds.[4]

[3] The term "primary barite," as used in this chapter, applies to barite as first offered to the trade, whether lump, crushed, or ground. Where ground barite has been reported to the Bureau of Mines as original production, an estimate of the value of the lump equivalent of the ground has been assigned to such tonnage.
[4] Oil, Paint and Drug Reporter, vol. 156, No. 20, Nov. 14, 1949, p. 41.

California.—Crude barite from the mine of Baroid Sales Division of National Lead Co., near El Portal, Calif., was ground in its plant at Merced.

Georgia.—The barite deposits in the Cartersville district, northwestern Georgia, were described.[5] New Riverside Ochre Co. and Paga Mining Co. continued to produce near Cartersville. B. R. Cain reported cessation of operations at his mine near Cartersville in 1949. Operators in this area report severe competition from imported barite.

Idaho.—J. R. Simplot Co. produced crude barite from the Sun Valley Barite mine near Hailey, Idaho, and ground this material at its plant at Pocatello for well-drilling use.

Kentucky.—Deposits of mixed barite and fluorspar of widely varying composition occurring in Kentucky are mined and sold to the glass industry as a flux. One commercial product analyzes about 40 percent $BaSO_4$ and 60 percent CaF_2.[6] This production is not considered in the barite statistics but is included in the fluorspar statistics.

Missouri.—Many Missouri producers were inactive during a part of 1949 as a result of the slack demand for barite.

Nevada.—Several new producers in Nevada reported shipments of barite during the year.

New Mexico.—It was reported that the Royal Flush mine in the Hansonberg district of Socorro County, N. Mex., was sold to Erwin & Bishop of Houston, Tex., who plan to build a barite cleaning, grinding, and sacking plant near San Antonio, N. Mex., south of Socorro.[7]

Mudrite Chemical Corp. temporarily ceased operations at its mine near Hatch and plant at Rincon on April 30.

Discovery of a deposit of barite near Albuquerque was reported.[8]

South Carolina.—Industrial Minerals, Inc., purchased the properties of Cherokee Chemical Co., at Kings Creek, S. C. The plant at this property was formerly operated under lease by the Clinchfield Sand & Feldspar Corp. Local barite ore will be utilized instead of ore from Tennessee which was formerly processed in this plant.

Tennessee.—Operations of the Clinchfield Sand & Feldspar Corp. near Del Rio, Tenn., were discontinued in January.

The Bureau of Mines issued a report on the results of a diamond-drilling project on three properties in eastern Tennessee and western North Carolina conducted during 1944 as a part of the strategic minerals program.[9]

CONSUMPTION AND USES

The consumption of barite in the United States in 1949 was reported as follows (1948 in parentheses): For well drilling, 494,579 short tons

[5] Kesler, Thomas L., Occurrence and Exploration of Barite Deposits at Cartersville, Ga.: Min. Eng., vol. 1, No. 10, October 1949, Trans. Am. Inst. Min. and Met. Eng., vol. 184, 1949, pp. 371–75.

[6] Ceramic Industry, vol. 52, No. 1, January 1949, p. 107.

[7] Engineering and Mining Journal, vol. 150, No. 6, June 1949, p. 116.

[8] Engineering and Mining Journal, vol. 150, No. 4, April 1949, p. 127.

[9] Dahners, Laurence A., Investigation of the Del Rio and Stackhouse Barite Deposit, Cocke County, Tenn., and Madison County, N. C.: Bureau of Mines, Rept. of Investigations, 4571, 1949, 26 pp.

(565,249); for lithopone, 71,710 (153,987); for chemicals, 80,584 (100,038); for glass, 21,768 (23,580); for paint filler, 20,000 (22,000); for rubber filler, 14,000 (18,000); and for other purposes, including grinding losses, 16,902 (11,455); total, 719,543 (894,309). These figures include both foreign and domestic barite.

Total barite consumed in the United States during 1949 was the lowest in several years. The bulk of the ground barite was used in well-drilling muds. In recent years many new records have been set in the depths to which oil wells are drilled, and the average depth of wells drilled is increasing steadily. Such a situation requires more and improved drilling muds in which ground barite is used principally as a weighting agent.

The greatest decrease in consumption was in lithopone. Titanium dioxide is replacing a large part of the lithopone as a white pigment in paints and other products.

Numerous new barium compounds and new uses for barium compounds are being developed. Among these are barium phenolate, a chemical starting point in the manufacture of plasticizers,[10] barium compounds sprayed on the cathode of voltage regulation tubes,[11] the use of radioactive barium isotopes in tracing of fluid flow through pipes,[12] and barium stearates.[13]

Crude barite (domestic and imported) used in the manufacture of ground barite and barium chemicals in the United States, 1945–49, in short tons

A considerable interest in the compound barium titanate and its dielectric and electrostrictive properties was expressed and a number of interesting articles[14] and patents[15] dealing with the properties, preparation, and uses of this compound have been published in recent years.

[1] Of any barium chemical.
[2] Includes purchased material.
[3] Exclusive of purchased material and exclusive of sales by one producer to another.
[4] Black-ash data include lithopone plants.
[5] Included with "Other barium chemicals."
[6] Consists mostly of titanium dioxide-barium sulfate pigments (except 1949), with small quantities of barium acetate, chromate, nitrate, perchlorate, peroxide, and sulfide. Specific chemicals may not be revealed by specific years.
[7] Plants included in above figures.
[8] Also includes barium sulfate (synthetic).
[9] A plant producing more than 1 product is counted but once in arriving at grand totals.

PRICES

Trade-journal price quotations for crude and ground barite, witherite, and barium chemicals remained generally constant during 1949.

Crude.—The December 8, 1949, issue of E&MJ Metal and Mineral Markets quoted the following prices for crude barite, f. o. b. mines: Georgia, crude, $11.50–$12.00 per long ton; Missouri, crude, minimum

94 percent $BaSO_4$, less than 1 percent iron, $9.50 per short ton; 93 percent $BaSO_4$, $9.00–$9.25, f. o. b. mines.

Ground.—In December the price of water-ground barite in paper bags, carlots, St. Louis, remained at $35.05 per short ton the same as in 1948, according to Oil, Paint and Drug Reporter. Well-drilling grades of ground barite averaged $17.41 a short ton, bulk, f. o. b. mine, according to reports of grinders to the Bureau of Mines.

Witherite.—Witherite (barium carbonate) was quoted in 1949 at $65 per short ton, air-floated, carlots (the same as in 1948); $72–$73 on less than a carload.

Range of quotations on barium chemicals in 1949

[Oil, Paint and Drug Reporter]

Barium carbonate, precipitated, bags, 10 tons and up, works	short ton	$72.50 –$80.00
Barium chlorate, kegs, works	pound	.25½– .31
Barium chloride, technical, bags, carlots, works, freight equaled	short ton	90.00
Barium chromate, bags, freight equaled	pound	.31½– .32
Barium dioxide (peroxide), drums, carlots, works	do	.12
Barium hydrate, crystals, bags	do	.09 – .09½
Barium nitrate, barrels, carlots, works	do	.11½
Barium oxide, ground, drums, carlots, works	do	.11
Blanc fixe (dry):		
Direct process, bags, carlots, works	short ton	85.00
Byproduct, bags, carlots, works	do	77.50
Lithopone: [1]		
Ordinary, bags, carlots, shipping point	pound	.06¼– .06⅜
Less carlots, same basis	do	.06½ .06¾
Titanated (high-strength), bags, carlots, shipping point	do	.08¼
Smaller lots	do	.08½

[1] Pacific coast prices on lithopone ¼ cent per pound higher.

FOREIGN TRADE [16]

Barite.—Imports of crude barite were the lowest in several years. Canada remained the leading source, but tonnages shipped were

sharply reduced owing to the lack of markets. Yugoslavia shipped a large tonnage for the first time. Crude barite was also imported from Italy and Mexico and a small tonnage of ground barite from Greece.

As of October 5, 1949, Great Britain relaxed import-licensing restrictions on barite. The relaxation took the form of Open General Licenses permitting anyone to import goods without the need of an import license from any country other than the dollar-account countries.

Witherite.—All imports of witherite came from Great Britain.

Witherite, crude, unground, imported for consumption in the United States, 1945–49

TECHNOLOGY

A report summarized results of the ore-dressing studies and field geology investigation of the Carolina barite belt carried on by the North Carolina Department of Conservation and Development, the South Carolina Research, Planning, and Development Board, and the Regional Minerals Section of the TVA Division of Chemical Engineering.[17]

WORLD REVIEW

Argentina.—Barite mining and processing was declared "of national interest" by the Argentine Government. Accordingly, all imports of the mineral will be under Government control. Barite mining and processing, begun in that country in 1949, was developed during the war years to prove that domestic ore will be adequate to satisfy national consumption.[18]

World production of barite, by countries, 1944–49, in metric tons [1]

Brazil.—The barite deposits of Camamu Bay, Brazil, were described.[19]

Early in 1948, the management of the barite operations of the Pigmentos Minerals Industrial e Comercial Pigmina, S. A., on the island of Camamu, Baia, were taken over by a firm in Rio de Janeiro, and the name of the concern was changed to Antiles Minerals.[20]

Canada (Nova Scotia).—According to the American consulate at Halifax, the barite activity at Walton, in common with many other Canadian mining industries, experienced a mild business recession during midsummer of 1949, but operations soon returned to normal. The proven ore reserves are reported to approximate 1,600,000 long tons, and a heavy development program in progress is expected to augment these reserves. The company continued to reduce operating costs.

Progress made by Maritime-Barytes, Ltd., in establishing a plant at Brookfield for the production of high-grade white, as well as oil-grade, has been confined to revision of flow-sheet plans and preparations for plant construction expected to go forward in the spring of 1950.

Of various developments affecting mining activities in Nova Scotia, probably the most important was devaluation of the Canadian dollar and other currencies in mid-September. The barite industry, an export business in this Province, had been hard hit earlier in the year by slumping sales owing to complex market conditions, and the effect of dollar shortage abroad and greater devaluation by other producing countries was to close operations in the Province entirely.[21]

Barite deposits and operations in Nova Scotia were described in detail.[22]

France.—There are barite deposits in more than 30 Departments in France. For a long time, the two Departments with the most important production have been Lozère and Hérault. In the Basses-Pyrénées, use is being made of the deposit at Bidarray, where the mineral is of superior quality, containing less than 2 percent silica.[23]

Germany.—The war-damaged Hartenrod mine at Herborn, Baden, has been rehabilitated, and the Rhine River & Barite Works has resumed producing barite at the rate of 50 tons monthly. Before the war, this mine yielded approximately 2,000 tons each month, which found a market in the chemical, paint, and paper industries.[24]

The Barite mine at Muenden and the mill at Sontra, Hesse, of Deutsche Baryt-Industrie have ceased operations owing to lack of demand.[25]

Philippines.—A large barite deposit was discovered in the Province of Batangas. The ore appears to be high grade. Development is still in the exploration stage.[26]

Bauxite

By Richard H. Mote and Horace F. Kurtz

GENERAL SUMMARY

UNITED STATES, mine production of crude bauxite during 1949 totaled 1,352,495 long tons (1,148,792 tons, dried equivalent), a decrease of 22 percent from 1948. Curtailed operations during the second and third quarters and a work stoppage by one strike-bound producer reduced annual output to the lowest level since 1946. Arkansas mines produced nearly all of the domestic bauxite in 1949.

Imports constituted a larger proportion of the total supply than in previous years and even increased in tonnage in 1949, despite a decline in total bauxite consumption. Surinam supplied 75 percent of the imports (82 percent in 1948), but receipts from Indonesia represented the largest gain. For the sixth consecutive year exports of bauxite and concentrates, largely to Canada, decreased.

Domestic consumption of bauxite in 1949 was 2,667,043 tons (dried equivalent), slightly below 1948. Of this quantity, 86 percent was used at alumina plants. The prices for most grades of bauxite were changed little from 1948.

Stocks of crude bauxite declined during 1949, but those of bauxite already processed and ready for use accumulated at most producers' and consumers' plants. The War Assets Administration stockpile in Arkansas remained unchanged at 2,785,527 tons throughout 1949. Bauxite stocks in the National Stockpile were not disclosed.

Salient statistics of the bauxite industry in the United States, 1940–44 (average), and 1945–49

	1940–44 (average)	1945	1946	1947	1948	1949
Crude ore production (dried equivalent) .... long tons	2,606,980	981,009	1,104,054	1,202,055	1,457,148	1,148,792
Value of production	$12,894,650	$5,591,084	$6,892,864	$6,884,666	$8,696,708	$6,778,181
Imports (as shipped) .... long tons	947,726	739,581	852,005	1,821,580	2,488,915	2,688,164
Exports (as shipped) .... do	298,217	126,077	97,788	94,369	54,113	34,902
World production (as shipped) .... long tons	7,839,000	3,427,000	4,376,000	6,151,000	8,204,000	8,133,000

World output of bauxite was estimated at 8,133,000 long tons in 1949, compared with 8,204,000 tons (revised) in 1948. United States and the Guianas, principal producers in the Western Hemisphere, mined 61 percent of the 1949 total.

Aluminum metal is discussed in the Aluminum chapter of this volume.

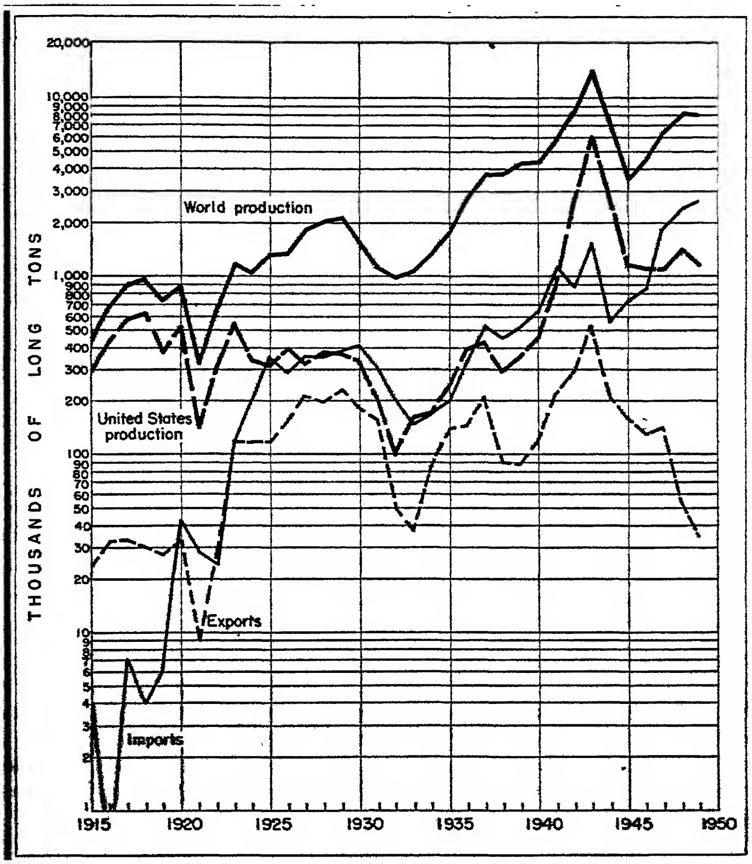

FIGURE 1.—Trends in domestic production, imports, exports, and world production of bauxite, 1915–49.

RESERVES

The Bureau of Mines and Geological Survey estimated[1] reserves of domestic bauxite at 36,341,000 long tons in 1944. This represented all deposits (measured or indicated) 8 feet or more in thickness in which the material did not exceed 15 percent SiO_2 or 6 percent FeO but did contain at least 40 percent Al_2O_3 recoverable bauxite on a mined and dried basis. These limits of analysis were the theoretical extremes for bauxite to be used in the production of alumina by wartime modifications of the Bayer process. Deduction of the quantity mined during the past 5 years reduced the total reserves to about 30,450,000 tons. The alumina plant at Hurricane Creek, Ark., is capable of processing bauxite of greater iron content than was included in the original estimate, and this fact may permit an increase

[1] Investigations of Natural Resources, Hearings Before a Subcommittee of the Committee on Public Lands, United States Senate, 80th Cong., 1st sess., 1947, pp. [illegible].

in the reserve figure. Results of experimental work to utilize low-grade bauxites for alumina production were published during 1949.[2]

DOMESTIC PRODUCTION

Domestic mine production of crude bauxite in 1949 declined 22 percent to 1,352,495 long tons (1,148,792 tons, dried equivalent). The decrease was attributed to a labor strike at the largest producer, a smaller demand from the aluminum industry resulting from reduced metal output, and the competition of higher-grade foreign ores. Bauxite production from mines in Alabama, Arkansas, and Georgia declined 23, 22, and 4 percent, respectively; Arkansas supplied 95 percent of the total output.

Production of bauxite in the United States by quarter years,[1] 1947–49, in long tons (dried equivalent)

Months	1947	1948	1949
January-March	323,180	295,488	320,157
April-June	301,561	359,284	294,023
July-September	282,665	437,457	208,926
October-December	294,649	364,919	325,686
Total	1,202,055	1,457,148	1,148,792

[1] Figures adjusted to final annual totals.

Alabama.[3]—Mines in the Eufaula district, Barbour and Henry Counties, Ala., were operated in 1949 by the Alcoa Mining Co. and the D. M. Wilson Bauxite Co. Ore produced by the Alcoa Mining Co. was dried at its plant adjacent to the mines and shipped to the chemical and refractory industries. Alabama bauxite was also processed at the activating plant of the Floridin Co., Quincy, Fla., from which it was shipped to oil-refining industries.

Arkansas.—The Alcoa Mining Co. reduced production from its mines near Bauxite, Saline County, Ark., by 15 percent in 1949 and from its smaller mining operations in Pulaski County by 6 percent. The Saline County mines were served by a drying and calcining plant from which ore was shipped in dried form, mostly to alumina but also chemical plants. In Pulaski County the Drury drying and calcining plant produced calcined bauxite for abrasives, as well as dried ore for the alumina and chemical industries.

Both the Berry-Mayhan and the Rauch Leased mines, situated in the Berger district, Pulaski County, were operated by the American Cyanamid Co. during 1949. All of the 1949 mine production, which totaled less than in 1948, together with shipments from stocks of the idle Heckler mine and purchases from another producer, were dried at the company plant near Berger. Most of the product was consumed in chemical plants, although part was used for oil refining.

Consolidated Chemical Industries, Inc., did not mine bauxite during 1949; however, ore was transferred from existing inventories at the Bierman Tract site, Pulaski County, to the Peiser Spur concen-

trating plant in Little Rock and, after treatment, shipped to the alumina industry.

The Crouch Mining Co. produced nearly the same tonnage of bauxite from its Young mine, Saline County, in 1949 as in the preceding year. Operations at the calcining plant near Bauxite, where ore is processed for the abrasives industry, were below the 1948 level.

Output from the Pulaski County mines of the Dulin Bauxite Co. declined substantially in 1949. Bauxite, not shipped directly to consumers or other processors, is calcined mainly for abrasive manufacture at the company plant in the vicinity of Sweet Home.

The Norton mine, Saline County, remained idle throughout 1949, but the calcining plant continued to operate, using ore from another producer. All of the calcined bauxite was used for making abrasives.

At its milling, activating, and purifying plant in Berger, Pulaski County, the Porocel Corp. activated crude ore, purchased from local producers, for sale chiefly to oil refineries. The Porocel plant for impregnating activated bauxite with chemicals did not operate during 1949.

The Reynolds Mining Corp. extracted bauxite from its mines in Saline and Pulaski Counties, and, despite decreased output in both localities, remained the largest domestic producer. A 2-month strike sharply curtailed operations during the third quarter. Output from these mines was sold undried to the parent Reynolds Metals Co. and converted to alumina at the Hurricane Creek plant.

Georgia.[4]—The only production of bauxite in Georgia during 1949 came from the American Cyanamid Co. Hatton and Thigpen mines in the Andersonville district, Sumter County. All of the ore was dried in the adjacent oil-fired standard-rotary-drying plant and shipped to the chemical industry.

Bauxite shipped from mines and processing plants in the United States, 1946–49, by consuming industries, in long tons

Tennessee.—No bauxite has been mined commercially in Tennessee since 1928. The Bureau of Mines has published results of a survey conducted in one area during World War II.[5]

CONSUMPTION AND USES

Consumption of bauxite for all purposes in 1949 decreased 2 percent to 2,667,043 long tons (dried equivalent). Total consumption figures include calcined bauxite shipped for export to American-owned abrasive plants in Canada for the manufacture of crude abrasives, which are returned to the United States for final manufacture and use. Bauxite consumption on an as-shipped basis totaled 2,691,171 tons, comprising 678,219 tons of crude ore, 1,882, 441 tons of dried bauxite, 123,511 tons of calcined bauxite, and 7,000 tons of activated bauxite. Of that consumed (dried equivalent basis) in 1949, 43 percent was from domestic sources and 57 percent from foreign. Approximately 79 percent of the domestic ore and 91 percent of the foreign were consumed by the alumina industry.

Bauxite consumed in the United States, 1948–49, by industries, in long tons

[Dried-bauxite equivalent]

Industry	1948			1949		
	Domestic	Foreign	Total	Domestic	Foreign	Total

[1] Includes some bauxite used in making chemicals and other products.

Alumina.—Four alumina plants—located at Mobile, Ala.; Hurricane Creek, Ark.; Baton Rouge, La.; and East St. Louis, Ill.—produced alumina from 86 percent of the total bauxite consumed. Aluminum metal was eventually extracted from most of this alumina, but part was used by the chemical, abrasive, and refractory industries and some was processed into special products, such as activated[6] and tabular aluminas, for use in the oil-refining and ceramic industries.

Chemical.—The use of bauxite for the production of aluminum salts dropped about one-tenth from 1948. In addition to bauxite, however, aluminum salts producers reported consuming 11,161 short tons of aluminum trihydrate, 4,458 tons of secondary aluminum, 79,164 tons of clay, and a small quantity of bichromate residues and other materials. Consumption of bauxite for the production of nonmetallurgical alumina is included with the figures for alumina in the preceding paragraph and table.

Alumina [2]	82,512	7	60,080	5,605,013	71,278	6	54,149	4,629,063

[1] A company shipping more than 1 kind of salt is counted but once in arriving at total.
[2] Excludes alumina produced for use in making aluminum; includes activated, calcined, and crude alumina and light and heavy hydrate, converted to a calcined-alumina equivalent.

Losses in production and shipments of aluminum sulfate were the leading factors in causing an over-all decline in totals for aluminum salts, as liquid aluminum chloride and sodium aluminate gained while most other salts were virtually unchanged. Value of shipments increased slightly, despite fewer companies reporting shipments. Output of alumina for purposes other than aluminum production was lowered 14 percent in 1949, and shipments to other consumers dropped 10 percent.

Abrasive and Refractory.—Manufacturers of refractories in the United States and aluminous abrasive pigs in Canada and the United States consumed 18 percent less bauxite in 1949 than in 1948. Retarded use of foreign ore for abrasives constituted the major change during 1949.

Other.—Consumption of bauxite in other fields, notably the cement, oil-refining, steel, and ferro-alloy industries, declined 18 percent in 1949.

STOCKS

Total inventories of bauxite on hand December 31, 1949, were 3 percent above stocks at the close of 1948. Mines and processing plants lowered inventories from 568,075 long tons (dried equivalent) at the beginning of the year to 502,338 tons, but inventories at consumers' plants totaled 873,731 tons at the end of 1949 compared with 669,698 tons on December 31, 1948. The large Government-owned (War Assets Administration) stockpile of medium-grade bauxite in Arkansas, on which Reynolds Metals Co. as operators of the Hurricane Creek alumina plant held option to purchase if needed, remained unchanged at 2,785,527 tons throughout 1949. All stock figures mentioned in this chapter exclude bauxite held by the Bureau of Federal Supply for the National Stockpile.

Stocks of bauxite on hand December 31, 1945–49, in long tons

[1] Dried, calcined, activated, and sintered.
[2] Excludes stocks in the National Stockpile.

PRICES

The average selling price in 1949, f. o. b. mines and processing plants, was $4.98 per long ton for crude (undried) bauxite, $7.58 for crushed dried bauxite, $16.31 for calcined bauxite, and $61.19 for activated bauxite. In 1948, corresponding prices were $5.08 per ton for crude, $7.50 for dried, $14.90 for calcined, and $57.93 for activated. The weighted average price for all grades of domestic ore as shipped to consumers was $6.68 per ton in 1949 ($6.69 in 1948). Nominal market quotations as published by E&MJ Metal and Mineral Markets were unchanged during 1949 at the following prices: Domestic ore, chemical, crushed and dried, 55 to 58 percent Al_2O_3, 1.5 to 2.5 percent Fe_2O_3, $8 to $8.50, f. o. b. Alabama and Arkansas mines; other grades, 56 to 59 percent Al_2O_3, 5 to 8 percent SiO_2, $8 to $8.50, f. o. b. Arkansas mines; pulverized and dried, 56 to 59 percent Al_2O_3, 8 to 12 percent SiO_2, $14 to $16, f o. b. Arkansas mines; abrasive grade, crushed and calcined, 80 to 84 percent Al_2O_3, $17, f. o. b. Arkansas mines; crude (not dried) 50 to 52 percent, $4 to $5, f. o. b. Arkansas mines. Quotations on foreign bauxite have not been published in domestic trade journals since February 1941.

FOREIGN TRADE [7]

Imports of bauxite gained 8 percent in 1949, the fifth successive year of increase, and established a new high record. Of the total receipts, 2,013,187 long tons were from Surinam, 575,137 tons from Indonesia, 99,821 tons from British Guiana, and 19 tons from Canada. By customs districts, receipts were as follows: 1,818,903 tons at Mobile, 807,880 at New Orleans, 24,281 at New York, 17,865 at Philadelphia, 8,630 at Massachusetts, 2,845 at Georgia, 2,756 at Sabine, 2,534 at Maryland, 2,435 at Virginia, and 35 at Buffalo. The duty remained unchanged throughout 1949 at 50 cents a long ton for crude and dried bauxite and at 15 percent ad valorem for calcined bauxite.

Exports of bauxite and bauxite concentrates were less than two-thirds of the 1948 total, as 1949 marked the sixth year of uninterrupted decrease. Bauxite and other aluminum ores comprised 34,235 tons of the 1949 shipments, and only 667 tons were classified as bauxite

[7] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

concentrates (including alumina). Virtually all the bauxite exported went to Canada to be used in the production of crude abrasives, which are returned to the United States for final manufacture and consumption. Canada also received 264 tons of the bauxite concentrates, while Iran received 180 tons and 7 other countries the remainder.

WORLD REVIEW

The world production of bauxite in 1949 was estimated slightly below that of 1948. A substantial production gain was achieved in Indonesia; however, output declined in each of the four leading countries. The United States, together with Surinam and British Guiana, mined 61 percent of the world total, compared with 66 percent in 1948.

Austria.[5]—Although bauxite is known to occur elsewhere in Austria, it is mined only at Unterlaussa. Production from this deposit, worked by the Germans during World War II, was resumed in 1948 and increased in 1949. Most of the ore from Unterlaussa is consumed by the abrasive and iron and steel industries.

British Guiana.—Output of bauxite in British Guiana declined approximately 6 percent in 1949, but the colony remained the world's

[5] Bureau of Mines, Mineral Trade Notes: Vol. 30, No. 1, January 1950, pp. 4–5.

second largest producer. Most of the exports were shipped from the Demerara Bauxite Co. to its affiliate, the Aluminum Co. of Canada.

[1] Bauxite is also produced in French West Africa, but production data are not available and no estimate is included in total.
[2] Data not available; estimate by junior author of chapter included in total.
[3] Estimate.
[4] Exports.
[5] Imports into Japan, Formosa, and Korea in fiscal year ended Mar. 31 of year following that stated; preliminary figures.
[6] Imports into Japan and Formosa in fiscal year ended Mar. 31 of year following that stated; preliminary figures.

France.—Reflecting in part the decrease in aluminum output in France during 1949, bauxite production was approximately 4 percent below the 1948 total. According to revised estimates, reserves of French ore were placed at 15 million tons of high-grade bauxite and 60 million tons classified as siliceous bauxite. Most of the ore mined has been converted to alumina, although suitable ore has been found for nearly all of the bauxite-consuming industries.

Hungary.—Increased mining of bauxite in Hungary during 1949 foreshadowed the nation's return to a position as one of the leading suppliers of aluminum ore. Markets in other central European countries and Russia, as well as the return of demand from Germany, formerly the destination of most Hungarian bauxite, indicated permanence in the growing industry. In accordance with plans for a larger aluminum industry, a greater proportion of bauxite was processed within Hungary than heretofore, but exports still exceeded domestic consumption in 1949.

Indonesia.—Output of bauxite on Bintan Island in Indonesia during 1949 gained 55 percent and reached a new record. United States was

the principal recipient of the ore exported, and most of the remainder was shipped to Japan.

Italy.—Since the loss of Istria to Yugoslavia, Italy's domestic bauxite mining has been largely in the Foggia and Bari areas. About 90 percent of the 1949 production, which was considerably below 1948, was mined from Montecatini holdings. A trade agreement with Yugoslavia guaranteed supplies from Istria and provided the major portion of Italy's approximately 85,000 metric tons of bauxite imports in 1949.

Jamaica.—Much interest has developed in the low-silica, high-iron bauxite deposits of Jamaica, both as a result of diminishing reserves in United States and because of the strategic importance of aluminum ore nearer the United States than the Guianas. Deposits under consideration were reported having little overburden and located not far from the seacoast. At the close of 1949, Reynolds Metals Co. and two subsidiaries were completing a contract with the Economic Cooperation Administration for Marshall Plan and ECA counterpart funds to help finance the purchase and installation of mining, milling, and transportation equipment. Kaiser Aluminum & Chemical Corp. investigated the utilization of deposits on which it acquired options, and the Aluminum Co. of Canada was also known to have deposits on the island.

Spain.[9]—Although the Spanish aluminum industry has relied mainly upon foreign ore in past years, increased mining during 1949 reflected plans for utilizing domestic bauxite in new plants. Ore reserves occur in the Provinces of Barcelona, Tarragona, Lérida, and Teruel.

Surinam.—The Moengo and Paranam mines of the Surinaamsche Bauxiet Maatschappij produced over 80 percent and the N. V. Billiton Maatschappij the remainder of the total bauxite output of Surinam in 1949, which was slightly below the foregoing year. Delays were attributed to heavy rains and a strike for increased wages at the Billiton mine. The Rickanau deposit, reported to compare favorably with Moengo in extent and grade of ore, was connected to the Moengo mill by completion of a 9-mile railroad during 1949. A revised tax system[10] affecting bauxite mining was instituted by the Surinam Government.

Bismuth

By Jack W. Clark

GENERAL SUMMARY

GOVERNMENT-financed purchases of refined metal, both for the National Stockpile and for United Kingdom and continental consumers under the European Recovery Program, served to stabilize the market for bismuth in 1949. Sustained high output of primary lead, from which most domestic bismuth is won as a byproduct, resulted in a total production of bismuth metal about equal to that in 1948. Imports, mostly from Peru, were the largest on record. Exports declined 46 percent below 1948. Producers' stocks rose 25 percent. The fission of bismuth with high-energy neutrons was a matter of considerable interest in nuclear research.

DOMESTIC PRODUCTION

Virtually all domestic production of bismuth is derived as a by-product from the smelting of lead ores and the refining of imported bismuth bars containing lead as a major impurity. The total quantity of metal recovered in 1949 rose slightly above 1948, reflecting a continued high rate of activity at primary lead smelters.

Companies reporting output of refined bismuth metal in 1949 were the American Smelting & Refining Co., Omaha, Nebr., and Perth Amboy, N. J.; Anaconda Copper Mining, Co., Anaconda, Mont.; and U. S. S. Lead Refinery, Inc. (subsidiary of United States Smelting, Refining & Mining Co.), East Chicago, Ind. Cerro de Pasco Copper Corp. is the principal domestic producer of bismuth alloys at its Brooklyn, N. Y., works; bismuth metal used is obtained from the company lead smelter at La Oroya, Peru.

CONSUMPTION AND USES

Demand for bismuth, particularly in the form of refined metal, was firm in 1949. Producers' domestic sales were 7 percent above those in 1948. Purchases for the National Stockpile are believed to have been substantial. Bismuth compounds were reported in plentiful supply in 1949.

Bismuth metal is consumed mainly in the compounding of low-fusibility, bismuth-rich nonferrous alloys and of pharmaceuticals used principally for the treatment of stomach disorders. The fusible alloys of greatest utility contain 40 to 60 percent bismuth, with varying proportions of other metals, such as tin,[1] lead, cadmium, antimony,

[1] Tin Research Institute (Greenford, Middlesex, United Kingdom), Fusible Alloys Containing Tin: September 1949, 24 pp.

indium, and zinc. Alloys of this type have become strategic because of their time-saving applications in the aircraft, machine-tool, and automotive industries. A few important uses are in the bending of thin-walled tubing, spotting and securing of dies and punches, pattern-making, and electroforming.

Bismuth is employed to a small extent in the preparation of phosphors,[2] selenium rectifiers, special solders, and safety devices. The newly developed Standfast (British) metal machine for continuous vat dyeing of textiles uses a bath of molten bismuth alloy as a color-fixation medium.

Percentage distribution of bismuth consumed in the United States, 1945–49, according to major use group [1]

Use group	1945	1946	1947	1948	1949
Pharmaceuticals	51	63	52	49	31
Alloys [2]	49	37	48	51	69

[1] Computed from figures compiled by Civilian Production Administration and U. S. Department of Commerce, 1945–46, and by Bureau of Mines, 1947–49.
[2] Principally fabricating alloys but includes ammunition solders, fuse alloys, aluminum alloys, and other minor compositions.

STOCKS

Domestic producers' inventories of refined bismuth metal at the end of 1949 increased 25 percent above the same 1948 period. High-grade metal was actively sought during the year for the National Stockpile.

PRICES

Refined bismuth metal was quoted by E&MJ Metal and Mineral Markets at $2 per pound, ton lots, throughout 1949. This price has remained unchanged since it was established in February 1947. The Metal Bulletin (London) quotation for high-purity metal, per pound, 5 cwt. minimum, held steadily at 10s. 9d. for the first half of 1949, subsequent fluctuations being recorded as follows: June 14, 10s. 6d.; September 20, 10s.; October 4, 12s. 3d.–14s. 6d. Bismuth ore, per pound of contained metal, c. i. f., was quoted late in December 1949 at 9s. 6d., 65 percent minimum Bi, scaling downward to 1s. 3d. for ore assaying below 20 percent.

In December 1949, Cerro de Pasco Copper Co., largest United States producer of bismuth alloys, quoted the following prices per pound, in 100-pound lots or more, f. o. b., for various of its trade-marked alloys: Cerrobase, $1.17; Cerrobend, $1.36; Cerrocast, $1.37; Cerromatrix, $1.19; Cerrosafe, $1.20; and Cerrotru, $1.53. Cerrolow 105 and Cerrolow 117, each containing an appreciable indium content, were quoted, respectively, at $7.92 and $7.61 per pound, in lots of 1 pound or larger.

FOREIGN TRADE[3]

Imports.—Receipts of refined metal in 1949 showed an abrupt rise of 81 percent above 1948 and were the highest on record. The approximate percentage distribution of receipts by countries of origin was: Peru 78, Canada 10, Yugoslavia 8, Japan 2, and Korea 2 percent. Base-bullion (bismuth bars containing lead and other impurities) shipments to United States smelters declined about 98 percent below the abnormally high year 1948.

Exports.—Outgoing shipments of bismuth metal and alloys in 1949 slumped 46 percent below a year earlier. The United Kingdom was again the principal recipient, taking 138,765 pounds; France received 41,926 pounds. The metal shipped to France is believed to have been purchased with funds allocated for such use by the Economic Cooperation Administration in the latter part of 1948 under the European Recovery Program. Since 1937, the first year of record, United States exports of bismuth metal have ranged between an estimated peak of 900,000 pounds in 1937 to a low of 10,161 pounds in 1944.

Bismuth metal and alloys imported into and exported from the United States, 1945–49

[U. S. Department of Commerce]

Year	Imports of refined metallic bismuth		Exports of metal and alloys	
	Pounds	Value	Pounds	Value
1945	333,231	$316,135	115,543	$149,031
1946	422,336	464,922	153,058	173,463
1947	310,561	480,808	240,833	452,147
1948	299,824	464,733	352,027	711,354
1949	541,852	833,940	190,882	356,576

TECHNOLOGY

Bismuth is fissionable when bombarded with high energy nuclear particles;[4] the relative yields of the fission products were noted.

The constitutions of bismuth-antimony[5] and bismuth-indium[6] alloys and the electrical properties of bismuth oxide[7] were studied. The problem of copper embrittlement by traces of bismuth was the

subject of several papers.[8] The extractive metallurgy of bismuth was studied [9] and equipment and operation of a small bismuth refining plant described.[10]

WORLD REVIEW

Australia.—The prices of bismuth ores and concentrates in 1949 were fixed by the Commonwealth Prices Commission as follows: 13s. 4d. per pound of metal contained in material assaying 70 percent Bi or better, the price being scaled downward 1d. per pound for each unit below 70 percent until a minimum of 20 percent bismuth is reached.[11] The possibility of commercial recovery of bismuth and copper, along with gold, at Tennant Creek, Northern Territory, was discussed.[12] Bismuth oxides and carbonates are widespread, invariably accompanying high gold values. Several thousand tons of ore averaging 0.4 percent Bi were reported blocked out.

Canada.—Consolidated Mining & Smelting Co. of Canada, Ltd., principal Canadian producer of bismuth metal, reported its total output for the periods 1894–1939 and 1940–49, inclusive, at 677 and 1,029 short tons, respectively. Domestic consumption of metal was 71 tons in 1947 and 44 in 1948; for the same years, producers' exports totaled 61 and 79 tons.

Korea.—The mill feed at the tungsten concentrator of the Sang Dong mine near Seoul contains about 0.2 percent of bismuthinite, which is recovered as a byproduct.

Uganda.—1949 output of bismuth ore from the Nyakashunzu mine was 6.88 tons; several more tons were obtained from another bismuth area west of Nyakashunzu. At the year-end production of bismuth ore was reported on the verge of rapid expansion.[13]

United Kingdom.—Activities of Mining & Chemical Products, Ltd., one of the world's largest producers of bismuth metals and alloys, were described.[14]

Cadmium

By Richard H. Mote

GENERAL SUMMARY

CADMIUM experienced an economic position unique among most metals during 1949. Consumer demand remained strong despite the general industrial recession in midyear, and the market price for commercial sticks continued unchanged at $2. A record peacetime output of primary metal, 6 percent greater than in 1948, and a sixteen-fold increase in metal imports expanded the total domestic supply sufficiently to meet requirements and yet maintain the proper balance between supply and demand necessary to prevent fluctuations in market quotations. Sales of metallic cadmium advanced 3 percent over 1948 and nearly equaled production. Industry stocks, sharply reduced in 1948, were replenished in 1949, and the Federal Government continued to purchase metal for the National Stockpile. As a result, the apparent industrial consumption declined 14 percent from the 1948 level.

Salient statistics of the cadmium industry in the United States, 1940–44 (average) and 1945–49, in pounds of contained cadmium

	1940-44 (average)	1945	1946	1947	1948	1949

[1] 1942–44 average.
[2] Actual consumption.
[3] Revised figure.

DOMESTIC PRODUCTION

As cadmium minerals—the most common of which is greenockite (CdS, 77.8 percent cadmium)—are too rare in occurrence to support profitable mining, no ore is mined or concentrated for the recovery of cadmium alone. The metal is recovered entirely in the mining, milling, and smelting of sulfide ores containing zinc mineralization and is obtained chiefly from the zinc sulfide sphalerite (ZnS), on which greenockite occurs as a yellow stain or coating. Although some zinc concentrates have been reported to contain as much as 1 percent cadmium, the content seldom exceeds 0.5 percent. Zinc concentrates from the tri-State region average 0.35 percent cadmium, and concentrates from mines in the Rocky Mountain region and far West rarely carry more than 0.2 percent cadminm.

The entire domestic supply of primary cadmium is recovered concurrently with the treatment of ores of other metals as a byproduct from the flue dusts of zinc-blende roasting furnaces and lead blast furnaces, from zinc dust collected in the early stages of distillation in zinc retorts, and from the high-cadmium precipitate obtained in purifying zinc electrolyte at electrolytic zinc plants. A small quantity of secondary metal is recovered from old bearings and other alloys but constitutes no great portion of the total supply. As most reduction plants participating in the recovery of cadmium treat both domestic and foreign cadmium-bearing materials without determining the cadmium content of either, the geographic origin of the metal produced from domestic plants is a matter of conjecture. Thus the data presented as domestic cadmium production in this chapter are not comparable to those given in other chapters of this volume for metals like copper, lead, and zinc.

Cadmium produced and shipped in the United States, 1940–44 (average) and 1945–49, in pounds of contained cadmium

	1940–44 (average)	1945	1946	1947	1948	1949

[1] Excludes compounds made from metal.
[2] Bureau of Mines not at liberty to publish figures separately for secondary cadmium compounds.
[3] Value of metal contained in compounds made directly from flue dust or other cadmium raw materials (except metal).

The domestic output of primary metallic cadmium, the production of cadmium contained in primary compounds, and the recovery of cadmium in secondary metal and compounds increased 6, 82, and 43 percent, respectively, in 1949.

A list of plants producing cadmium metal in the United States in 1949 follows:

Primary metallic cadmium

Colorado: Denver—American Smelting & Refining Co.
Idaho:
  Bradley—Bunker Hill & Sullivan Mining & Concentrating Co.
  Kellogg—Sullivan Mining Co.

Illinois: Fairmont City—American Zinc Co. of Illinois.
Missouri: Herculaneum—St. Joseph Lead Co.
Montana: Great Falls—Anaconda Copper Mining Co.
Oklahoma:
Bartlesville—National Zinc Co., Inc.
Henryetta—Eagle-Picher Mining & Smelting Co.
Pennsylvania:
Donora—American Steel & Wire Co.
Josephtown—St. Joseph Lead Co.
Palmerton—New Jersey Zinc Co.
Texas:
Corpus Christi—American Smelting & Refining Co.
Dumas—American Zinc Co. of Illinois.

Secondary metallic cadmium

Arkansas: Jonesboro—Arkansas Metals Co.
New York: Whitestone—Neo-Smelting & Refining, Inc.
Rhode Island: West Warwick—Rare Metals, Inc.

The cadmium content of the cadmium oxide produced advanced 71 percent but the content of the sulfide output dropped 9 percent. Data for the production of other cadmium compounds are not available for 1949.

Cadmium oxide and cadmium sulfide produced in the United States, 1945–49, in pounds

Year	Oxide		Sulfide [1]		Year	Oxide		Sulfide [1]	
	Gross weight	Cd content	Gross weight	Cd content		Gross weight	Cd content	Gross weight	Cd content
1945	439,415	383,553	1,731,516	637,667	1948	334,859	291,847	3,137,035	1,096,770

1947	449,847	392,556	3,501,508	1,308,285					

[1] Includes cadmium lithopone and cadmium sulfoselenide.

CONSUMPTION AND USES

The apparent consumption of primary cadmium in all forms totaled 7,676,800 pounds in 1949, as computed by adding production and net imports and adjusting for producers', distributors', and compound manufacturers' stock changes. This quantity was 2 percent less than the apparent consumption of 7,797,105 pounds in 1948. In both 1948 and 1949 cadmium metal was purchased by the Federal Government for the National Stockpile. Allowing for these Government withdrawals, the apparent industrial consumption of cadmium in 1949 was 14 percent under 1948 and over 30 percent less than the peak quantity used in 1945.

By far the largest single use of cadmium is for electroplating iron, steel, and, to a much smaller extent, copper alloys. The metal is desired for this use because (1) a thin coating is adequate to provide the necessary protection against corrosion; (2) cadmium has a high

Properties of cadmium compounds

Name and formula of compound	Molecular weight	Appearance	Specific gravity	Melting point, °C.	Boiling point, °C.	Soluble in—	Manufacture	Use
Cadmium acetate ($Cd(C_2H_3O_2)_2 \cdot 3H_2O$).	284.55	Colorless, monoclinic crystals.	2.01	256 (becomes anhydrous at 130).		Water and alcohol	Dissolve cadmium metal, CdO, or $Cd(OH)_2$ in acetic acid; evaporate solution to incipient crystallization.	To produce iridescent effects on porcelain and pottery ware; chemical testing for sulfides, selenides, and tellurides.
Cadmium bromide ($CdBr_2$).	272.24	Yellow, crystalline powder.	5.20	567	963	Water, alcohol, and HCl; slightly soluble in acetone and ether.	Dissolve cadmium metal in bromine water acidified with hydrogen bromide to prevent formation of basic salts; or dissolve $CdCO_3$ in aqueous hydrogen bromide and evaporate solution to dryness.	Photography, lithography, and process engraving.
Cadmium carbonate ($CdCO_3$).	172.42	White, crystalline powder.	4.26	Decomposes below 500.		Acids, potassium cyanide, and ammonium salts.	Add an alkali carbonate to a solution of a cadmium salt.	Starting compound for other cadmium salts.
Cadmium chloride ($CdCl_2$).	183.32	Colorless, hexagonal crystals.	4.05	568	960	Water, methanol, and ethyl alcohol.	Dissolve cadmium metal in an aqueous solution of HCl and evaporate in a stream of HCl gas; or dissolve CdO or $CdCO_3$ in HCl.	Reagent in photography; analysis of sulfides; testing for pyridin bases; ingredient in cadmium plating electrolytes; mordant in dyeing and printing calicoes.
Cadmium hydroxide ($Cd(OH)_2$).	146.43	White powder	4.79	Decomposes at 300.		Dilute acids and in ammonia salts. Readily absorbs CO_2 to form $CdCO_3$.	Add ammonium hydroxide to solution of a cadmium salt, producing gelatinous precipitate with the formation of the complex ammonia ion. To obtain purest material, precipitate from a nitrate solution, for it absorbs the nitrate ion less strongly than either the chloride or sulfate ion.	Manufacture of cadmium salts.

Properties of cadmium compounds—Continued

Name and formula of compound	Molecular weight	Appearance	Specific gravity	Melting point, °C.	Boiling point, °C.	Soluble in—	Manufacture	
Cadmium iodide (CdI_2)	366.25	Brownish, lustrous, hexagonal scales.	5.67 (α) 5.30 (β)	388 -	713 -	Water, acids, ether, alcohol, ammonium salts.	Heat cadmium metal with iodine, or treat a cadmium compound with a solution of hydrogen iodide.	Photography, lithography, and process engraving.
Cadmium oxide (CdO_2)	128.41	Light-brown to yellowish brown to dark-brown cubic crystals or amorphous powder, depending upon method of preparation.	8.15 (cubic form). 6.95 amorphous).	Above 1,426 Decomposes at 900.	Decomposes at 900–1,000.	Acids and ammonia salts.	(1) Distill pure cadmium metal in graphite retort, and permit vapor to react with air. (2) Heat $CdCO_3$ or $Cd(NO_3)_2 \cdot 4H_2O$ temperature of thermal decomposition to form CdO_2.	Cadmium plating baths; manufacture of paint pigments; coating for luminescent powders, such as cadmium sulfide and zinc sulfide; active ingredient in negative plates of nickel-cadmium batteries.
Cadmium nitrate ($Cd(NO_3)_2 \cdot 4H_2O$).	308.49	White, hygroscopic crystals.	2.46	594	132	Water, alcohol, and liquid ammonia.	Dissolve the metal, CdO_2, or $CdCO_3$ in HNO_3, and evaporating to incipient crystallization.	Imparts a reddish yellow cadmium luster to glass and porcelain ware.
Cadmium sulfate ($3CdSO_4 \cdot 8H_2O$).	769.54	Colorless, monoclinic, efflorescent crystals	3.09	-	-	Water	Dissolve metal in H_2SO_4, CdO_2 or $CdCO_3$.	Reagent to determine H_2S and detect fumaric acid; as an electrolyte in standard cadmium electric cells; in medicine for diseases of the eye, for corneal opacities, conjunctivitis leucoma.
Cadmium sulfide (cadmium yellow) (CdS).	144.47	Amorphous, yellow, orange, or brown powder. Dimorphous crystals in lemon-yellow or vermilion.	3.91–4.15 (α). 4.48–4.51 (β).	-	-	Acids	(1) Heat CdO_2 with sulfur. (2) Pass H_2S through acid solution of cadmium salt (better-quality producer). (3) Dissolve CdO_2 in H_2SO_4, CdS precipitated from this solution by H_2S.	Pigment in paints requiring high-quality yellow pigments: coloring vulcanized rubber, artists' colors, soaps, glass, textiles, paper, printing inks, ceramic glazes; ingredient of ultra-marine green and fluorescent pigments.

rate of deposition; (3) the metal has a high throwing power (the property of depositing uniformly on intricately shaped objects); (4) cadmium is capable of imparting an enduring metallic luster to the electroplated item; and (5) cadmium has high resistivity to atmospheric, alkali, and salt-water corrosion. A disadvantage of cadmium plating is its low resistance to acids. Items commonly electroplated with cadmium include nails, screws, rivets, bolts, nuts, washers, fasteners, and miscellaneous parts for a wide variety of products, including aircraft, ordnance, and automobiles.

Another large use of cadmium metal is in the manufacture of bearing metals. Cadmium-base bearing metals containing 98.3 to 98.5 percent cadmium and varying quantities of nickel, silver, or copper, depending upon the type of bearing desired, are used successfully in internal-combustion engines that operate at high speeds and temperatures.

Small quantities of cadmium metal are consumed for the manufacture of solders and other alloys.

Cadmium is consumed in the manufacture of a number of compounds having a wide variety of uses. The accompanying table lists the more important cadmium compounds, their physical properties, and uses.

STOCKS

Total domestic stocks of cadmium metal and compounds increased 51 percent in 1949. Details are given in the following table.

Cadmium stocks at end of year, 1948–49, in pounds of contained cadmium [1]

	1948 [2]			1949		
	Metallic cadmium	Cadmium compounds	Total cadmium	Metallic cadmium	Cadmium compounds	Total cadmium
Producers	351,564		351,564	509,019		509,019
Compound manufacturers	8,230	87,944	96,174	8,360	121,909	130,269
Distributors [3]	83,496	39,409	122,905	184,417	35,768	220,185
Total stocks [4]	443,290	127,353	570,643	701,796	157,677	859,473

[1] Excludes cadmium in National Stockpile.
[2] Figures partly revised.
[3] Comprises principally 8 largest dealers.
[4] Excludes consumers' stocks, which were about 1,000,000 pounds at the end of 1944 (latest date for which figures were compiled).

PRICES

The quoted New York price of $2 a pound for commercial sticks of cadmium, established November 15, 1948, remained unchanged throughout 1949. The price for patented shapes, quoted at $2.10 a pound since November 15, 1948, was adjusted upward to $2.15 a pound on April 1. The average price for domestic metal, as reported to the Bureau of Mines by primary producers, was $1.88 a pound in 1949, compared with $1.66 in 1948, $1.57 in 1947, 99 cents in 1946, 77 cents in 1945, and 75 cents in 1944.

The London market quoted 12s. 6d. ($2.42) per pound in January through mid-September, when quotations were suspended. Due to devaluation of the British pound on September 19, the price as announced the first week in October was 14s. 6d. ($1.97), at which level it remained the balance of the year.

FOREIGN TRADE[1]

In 1949 total imports for consumption of metallic cadmium and of cadmium contained in flue dust increased 6 percent in weight and 30 percent in value. The total value of exports fell off 34 percent owing to sharp declines in the quantity of exported metal and drosses, flue dust, residues, and scrap.

Imports.—Imports of cadmium-bearing flue dust, virtually all from Mexico, dropped slightly more than 2 percent from the 1948 rate. Imports of metallic cadmium, however, were over 16 times greater than the total imported in 1948 and the largest quantity recorded since 1939. Canada supplied over 43 percent of the metal imported in 1949, nearly 31 percent came from Belgium-Luxembourg, 20 percent from Japan, 5 percent from Australia, and 1 percent from Peru.

Cadmium metal and flue dust imported for consumption in the United States, 1947–49, by countries

[U. S. Department of Commerce]

Country	1947		1948		1949	
	Pounds	Value	Pounds	Value	Pounds	Value
Metallic cadmium						
Australia					7,210	$7,919
Belgium-Luxembourg	2,000	$7,073			48,503	101,560
Canada	14,612	20,551	6,300	$14,491	68,140	139,392
Japan					31,640	50,742
Peru	3,658	4,508	3,509	7,018	1,711	3,422
Switzerland	2	150				
United Kingdom	20	63				
Total metallic cadmium	20,292	32,345	9,809	21,509	157,204	303,035
Flue dust (Cd content)						
Australia			621	303		
Brazil					2,906	2,801
Mexico	2,355,588	1,673,153	1,827,518	1,437,833	1,786,761	1,593,142
Total flue dust	2,355,588	1,673,153	1,828,139	1,438,136	1,789,667	1,595,943
Grand total	2,375,880	1,705,498	1,837,948	1,459,645	1,946,871	1,898,978

Exports.—Countries in the Organization for European Economic Cooperation continued to receive substantial quantities of metallic cadmium from the United States in 1949, despite a drop of 41 percent in the exports of this item from the 1948 level. Of the 566,135 pounds of cadmium metal exported, France received 45, Germany 16, United Kingdom 8, Netherlands 7, and Sweden 6 percent; the remaining 18 percent went to 15 other countries.

[1] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Cadmium exported from the United States, 1947–49, gross weight, by kinds

[U. S. Department of Commerce]

Kind	1947		1948		1949	
	Pounds	Value	Pounds	Value	Pounds	Value
Dross, flue dust, residues, and scrap	18,251	$21,838	92,847	$55,247	500	$125
Metal	303,401	746,804	955,701	1,872,467	566,135	1,264,307
Alloys			1,506	2,657	3,000	6,150
Total		768,642		1,930,371		1,270,582

Tariff.—Action taken at the Geneva Trade Conference of 1947 reduced, as of January 1, 1948, the import duty on cadmium metal from 7½ cents per pound as established in the Canadian Trade Agreement of 1939 to 3¾ cents per pound. Cadmium contained in flue dust remained duty free in 1949.

WORLD PRODUCTION

World production of cadmium in recent years, insofar as data are available, is shown in the accompanying table.

World production of cadmium, by countries, 1942–49, in kilograms

Carbon Black

By D. S. Colby, F. S. Lott, and B. E. Oppegard

GENERAL SUMMARY

THE PRODUCTION of carbon black in 1949 declined 6 percent to 1,223, 636 thousand pounds, while sales declined 10 percent to 1,125,-410 thousand pounds. Producers' stocks during the year increased 98,218 thousand pounds to 216,461 thousand pounds.

Production decreased in all reporting States except New Mexico. Texas production declined 3 percent, but nevertheless produced 71.5 percent of all carbon black in the country. Contact-black production decreased by nearly 50 million pounds and furnace black by nearly 25 million pounds.

The decline in sales was confined principally to contact grades. Sales of furnace grades declined only 1 percent. Rubber companies purchased 767,131 thousand pounds, 103 million pounds less than in 1948. Sales to ink companies remained virtually unchanged, and paint companies purchased 3 percent more than in 1948. Export sales declined, for the first time since 1943, to 303,244 thousand pounds.

Stocks of contact black held by producers at the end of the year totaled 119,599 thousand pounds, up 91,953 thousand pounds from 1948. Stocks of furnace black increased 6,265 thousand pounds to 96,862 thousand pounds.

Average per pound ... cents	4. 02	4. 82	5. 36	5. 88	6. 10

The average yield of carbon black from natural gas declined again, though slightly, to 2.38 pounds per thousand cubic feet. The carbon-black industry consumed 427,892 million cubic feet of natural gas valued at 4.76 cents per thousand cubic feet. This average value is

0.03 cent per thousand above the value in 1948. In addition, 72,387,-000 gallons of liquid hydrocarbons were used as raw material compared with 44,600,000 gallons in 1948.

The average value at plants of all carbon blacks increased from 5.88 cents per pound in 1948 to 6.10 cents in 1949.

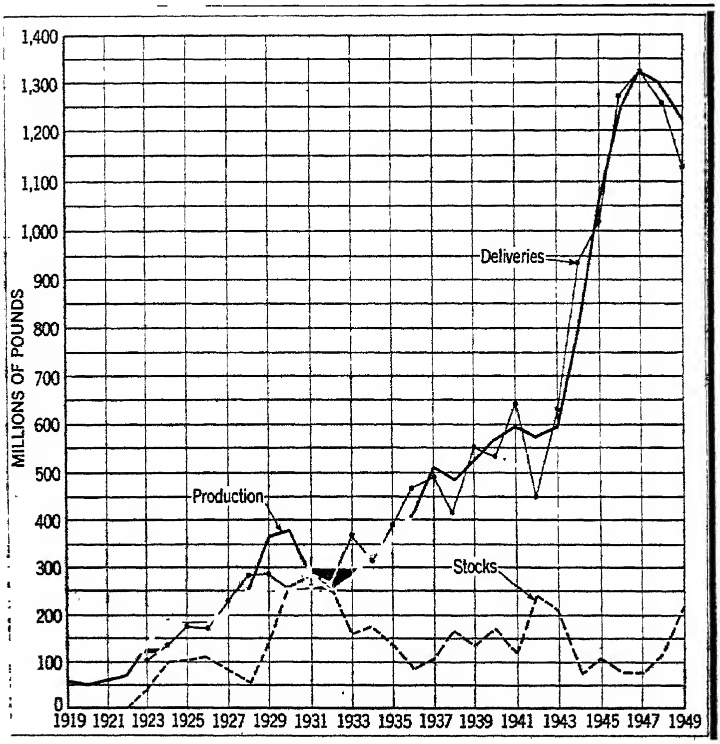

FIGURE 1.—Production, stocks, and deliveries of carbon black, 1919–49.

PRODUCTION

By States.—New Mexico was the only State whose production of carbon black increased in 1949. Production there increased 28 percent to 80,765,000 pounds. This increase, in the face of general production cut-backs, is attributed to the continued low price of gas in New Mexico. Large production declines were reported in Oklahoma (45 percent) and in California and Kansas (31 percent). Production in Texas declined slightly (3 percent), mostly in the Panhandle. Compared with the production of the entire country, the proportion produced by Texas increased nearly 2 percent to 71.5 percent. However, several channel plants in Texas were shut down during the year because of the adverse effect upon their competitive position of relatively high gas costs.

By Months.—Production of carbon black held steady through April 1949, declined rapidly in May and June, and then remained steady until November, when production again started upward. This pattern was followed in general by both contact-black and furnace-black production. Contact-black production declined 7 percent, and furnace-black production dropped 4 percent compared with 1948.

Carbon black produced from natural gas and liquid hydrocarbons in the United States, 1945–49, by States and districts, in thousand pounds

[1] Compiled from reports of the National Gas Products Association and of producing companies not included in the Association figures. Figures adjusted to agree with annual reports of individual producers.
[2] U. S. Department of Commerce.

Methods and Yields.—The average yield of carbon black from natural gas declined slightly in 1949 to 2.38 pounds per thousand cubic feet. This decline was caused by the pronounced reduction in yield of furnace black from natural gas, again probably owing to the production of a larger proportion of the fine-particle-size grades. A yield of 7.44 pounds per thousand cubic feet was obtained in 1949 compared with 8.07 pounds in 1948. The yield of contact blacks from natural gas continues to improve slowly, from 1.61 pounds per thousand cubic feet in 1948 to 1.67 in 1949.

The carbon-black industry consumed 427,892 million cubic feet of natural gas in 1949. Of this, 375,639 million cubic feet were used in the production of contact blacks.

The yield of carbon blacks produced from liquid hydrocarbons in 1949 was estimated to be 2.9 pounds per gallon. The total consumption of liquid hydrocarbons in the production of carbon blacks was 72,387,000 gallons, compared with 44,600,000 in 1948. Almost one-third of the total furnace black produced in 1949 was derived from liquid hydrocarbons, a striking growth made possible by superior quality and wide acceptance of the product of this relatively new process.

Number and Capacity of Plants.—The number of plants that operated during 1949 was 64, one more than in 1948. There were 44 contact-

Yield of carbon black, quantity and value of natural gas used, and number of producers of carbon black in the United States, 1945–49

type plants having a total reported capacity of 1,662,000 pounds per day and 20 furnace-type plants with a daily capacity of 2,163,800 pounds. This is a lower channel-type capacity and a slightly higher furnace-type capacity than operated in 1948.

Only one entirely new plant began operating in 1949—a furnace-type plant in Aransas County, Tex., operated by United Carbon Co., Inc. Parts of two channel-type plants were moved to new locations—one from Hutchinson County, Tex., to Richland Parish, La., and one from Moore County, Tex., to Lea County, N. Mex. The plant of Moore County Carbon Co. purchased by United Carbon Co., Inc., was moved from Moore County to Brooks County, Tex.

During 1949, two channel-type plants in Moore County, Tex., were combined; one channel-type plant in Grant County, Kans., a furnace-type plant in Evangeline Parish, La., and six channel-type plants in Texas were shut down. Of these six Texas plants, four are in Hutchinson County, one is on the border between Hutchinson and Carson Counties, and one is in Gray County.

Number and capacity of carbon-black plants operated in the United States, 1948–49

State or district	County or parish	Number of plants				Total daily capacity (pounds)

[1] One plant in both Carson and Hutchinson Counties tabulated with Hutchinson County.
[2] A plant moved from Hutchinson County, Tex., to Lea County, N. Mex., was counted as 2 plants in 1948.

Producers.—The number of producers in 1949 was 21, 3 less than in the previous year. The Columbian-Phillips Co. was dissolved. Its plant was dismantled and combined with a Columbian Carbon Co. plant. Witco Carbon Co. and Witco Hydrocarbon Corp. took over operation of the two Panhandle Carbon Co. plants. The name of Witco Hydrocarbon Corp. was subsequently changed to Barnhart Hydrocarbon Corp. Imperial Oil & Gas Products Co. sold its plant in 1948 to United Carbon Co., Inc.

DEMAND—SALES

Domestic deliveries of carbon black for all purposes declined 12 percent in 1949 to 822,166,000 pounds. Exports for the year were 303,244,000 pounds, resulting in a total demand of 1,125,410 pounds, 10 percent below that in 1948.

The trend of domestic sales by months was slightly downward for furnace blacks and steeply downward for contact blacks through September, after which sales of both types improved.

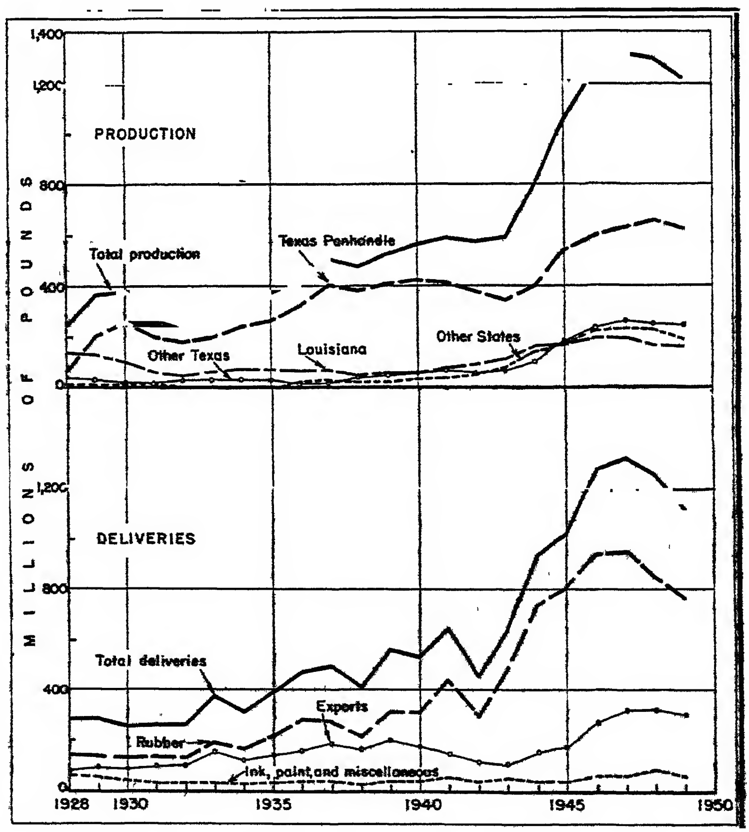

FIGURE 2.—Production and deliveries of carbon black, 1928–49. Production in "Other Texas" includes Oklahoma and Wyoming in 1932–35.

Total demand for furnace black in 1949 accounted for 52 percent of the demand for all types compared with 48 percent in 1948. Demand for furnace black decreased by 1 percent in 1949, while demand for contact types decreased by 19 percent. The renewed interest in furnace black can probably be attributed to the production of types more suitable for use in natural rubber.

The rubber industry again in 1949 consumed 93 percent of all carbon black sold domestically. Sales of carbon black to rubber companies decreased 12 percent, while consumption of virgin rubber declined 8 percent and reclaimed rubber declined 19 percent. If it is assumed, as in previous years, that 347 pounds of carbon black were consumed per long ton of reclaimed rubber, the carbon-black loading of virgin rubber in the United States was 698 pounds per long ton. This compares closely with a calculated loading of 706 pounds per long ton in 1948, as would be expected since the ratio of synthetic rubber to total virgin-rubber consumption remained unchanged at 0.42.

Sales of carbon black to ink manufacturers decreased 1 percent to 32,054,000 pounds. At the same time, newsprint consumption increased 8 percent to 5,529,000 tons, according to the American Newspaper Publishers Association.

The paint industry consumed 7,005,000 pounds of carbon black in 1949, 3 percent above 1948. The over-all output of the paint industry declined 6 percent.

Sales of carbon black for domestic consumption in the United States, by uses, 1945–49, in thousand pounds

Use	1945	1946	1947	1948	1949
Rubber	804,386	941,464	943,580	870,564	767,131
Ink	22,824	29,561	32,260	32,436	32,054
Paint	7,421	9,312	8,137	6,799	7,005
Miscellaneous	11,631	18,318	16,707	22,634	15,976
Total	846,262	998,655	1,000,684	932,433	822,166

STOCKS

Producers' stocks of carbon black rose throughout the year from 118,243,000 pounds on December 31, 1948, to 216,461,000 pounds at the end of 1949. This rise almost entirely affected stocks of contact blacks, which rose from a 16-day supply of 27,646,000 pounds at the beginning of 1949 to a 75-day supply of 119,599,000 pounds at the end of the year. The increases in these stocks during the last 2 months of 1949 were not as great as during the earlier part of the year.

Stocks of furnace blacks at the beginning of 1949 were 90,597,000 pounds, rising to 107,618,000 pounds in September and then declining to 96,862,000 pounds at the year end. The days' supply at the end of the year was 58 compared with 54 at the end of 1948.

Stocks of contact and furnace-type blacks held by producers as of December 31, 1944–49, were as follows, in pounds:

Year	Contact types	Furnace types	Total
1944 -----	58, 036, 000	11, 207, 000	69, 243, 000
1945 -----	64, 956, 000	37, 049, 000	102, 005, 000
1946 -----	17, 006, 000	59, 222, 000	76, 228, 000
1947 -----	8, 619, 000	66, 493, 000	75, 112, 000
1948 -----	27, 646, 000	90, 597, 000	118, 243, 000
1949 -----	119, 599, 000	96, 862, 000	216, 461, 000

PRICES

The average value of all carbon black produced in the United States in 1949 was 6.10 cents per pound f. o. b. producing plants compared with 5.88 cents in 1948. Contact blacks declined 0.06 cent per pound to 7.22 cents, while the average value of natural gas consumed at contact plants advanced 0.05 cent per thousand cubic feet to 4.74 cents.

The average value of furnace blacks increased from 4.35 cents per pound f. o. b. producing plants in 1948 to 4.92 cents in 1949. This rise in average value may have been caused in part by the production of a greater proportion of the fine-particle-size furnace blacks. The average value of natural gas consumed at furnace plants declined 0.07 cent per thousand cubic feet to 4.89 cents. The value of liquid hydrocarbons feedstock, for which figures are not available, is also an important factor in the average value of furnace blacks.

Oil, Paint and Drug Reporter on January 7, 1949, published a price increase of 0.08 cent per pound to 7.40 cents per pound for ordinary rubber grades of channel black in bags and fine furnace black in bags. On July 1, 1949, a price reduction of 0.50 cent per pound was reported for the ordinary rubber grades both in bags and bulk. This quotation places the price of these grades of channel black below that of fine furnace black for the first time since comparative prices have been available.

Prices of carbon black in carloads, f. o. b. plant, 1946–49, in cents per pound

[1] Chiefly easy-processing (EPC) and medium-processing (MPC) but also includes hard-processing (HPC) and conductive (CC) channel blacks.

[2] Office of Price Administration ceiling prices. Average realization on sales to the Rubber Reserve Company was generally higher.

FOREIGN TRADE [1]

Imports.—Imports of carbon black in 1949 consisted of 7,851,490 pounds from Canada, 409 pounds from Sweden, and 200 pounds from the United Kingdom. The Canadian imports consisted of 96,075 pounds of "gas black and carbon black" valued at 12.2 cents per pound and 7,755,415 pounds of "acetylene black" valued at 12.5 cents per pound. Both the quantity and unit value of acetylene black imports decreased from 1948, when they were 10,145,681 pounds at 12.7 cents per pound.

Exports.—Exports of carbon black declined in 1949 6 percent to 303,244,000 pounds. Export figures, by type of black, were available for the first time in 1949. Contact blacks comprised 68 percent of the

Carbon black exported from the United States, 1947–49, by countries

[1] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

exports compared with 40 percent of the domestic demand. The unit value of the exports was 8.84 cents per pound, virtually unchanged from the 1948 value of 8.86 cents.

Substantial increases were made in the quantities exported to France, Japan, Australia, and Brazil. France in 1949 was second only to the United Kingdom as an importer of American carbon black. Canada in 1949 dropped from second to third place.

Exports to the United Kingdom decreased by 31 million pounds and to Canada by 8 million pounds in 1949. Exports to the U. S. S. R. and its satellites—that is, China, Czechoslovakia, Hungary, and Poland—have stopped entirely or diminished to negligible amounts.

Current construction of carbon-black plants in the United Kingdom will undoubtedly cause further loss of export markets by 1951.

TECHNOLOGY

Two interrelated trends seem to be in progress in the carbon-black industry. One, already assuming importance, is the production of better furnace blacks. The other, still in the future, is dispersion of producing plants in this country and throughout the world.

Furnace blacks are being produced with reinforcing properties equivalent to or exceeding those of channel blacks. These can be produced more readily from liquid-petroleum fuels than from natural gas. These blacks are preferred over channel blacks for compounding with synthetic rubber stocks. Processing techniques and compounding formulations are being developed which produce desirable properties when these furnace blacks, in conjunction with channel black, are used in natural rubber stocks. The major difficulty in processing stocks incorporating furnace black is their low-scorch resistance, caused by the alkalinity and resultant low accelerator adsorption of these blacks.

The higher operating efficiency that can be achieved in the furnace process, about 50 percent for oil feed and 20 percent for gas feed, as compared to the 5-percent recovery with the channel process, makes this process more stable economically in the face of rising natural-gas costs.

Furnace plants using a liquid feedstock will not be tied to the gas fields as are the channel plants. Other economic factors can then determine the location of these plants. In some cases rail freight charges on carbon black from the gas fields to the rubber processing plant will be greater than transportation charges on equivalent liquid feed to a furnace plant at the rubber processing center. If the practice of incorporating carbon black in rubber latex becomes more common, furnace plants might advantageously be located at synthetic rubber plants or at the natural rubber plantation.

The two plants under construction in England to produce furnace black from liquid petroleum are indicative of the newly achieved independence of such facilities from natural-gas fields. These will begin production in 1951.

943785—51——14

WORLD REVIEW

The production of carbon black in countries other than the United States has been of minor importance. Before World War II a plant in the Baku oil fields of Russia produced about 2,000 tons per year, and small plants operated in Rumania, Czechoslovakia, and Yugoslavia. Recent production statistics are not available from these countries. Prewar Germany was the largest foreign producer, making about 30,000 tons a year from coal byproducts. Western Germany probably will produce around 20,000 tons in 1950 Austria is reported to be experimenting on the manufacture of carbon black from coal. England in the post-World War II years produced about 5,000 tons a year of lamp black, most of which was used in rubber compounding. Carbon black plants currently under construction in England will have a capacity of over 30,000 tons a year. The United States export market may be reduced by a corresponding quantity.

Cement

By D. G. Runner and Esther V. Balser

GENERAL SUMMARY

PRODUCTION of cement in 1949 increased over the previous year's total. Demand for cement during the year resulted in another record-breaking output, as 212,912,646 barrels of hydraulic cement were produced—2 percent more than in 1948. Nevertheless, production of one group of hydraulic cements (natural, masonry, and puzzolan cements) decreased slightly from the 1948 output. The portland-cement industry operated at 81 percent and the remainder of the hydraulic cement industry at 90 percent of productive capacity during 1949. Mill shipments of portland cement, which totaled 206,080,325 barrels, represented an increase of 1 percent over the 1948 figure—an all-time record. Shipments of other hydraulic cements decreased 4 percent. Stocks of all hydraulic cements on hand at mills December 31, 1949, amounted to 14,902,387 barrels, 32 percent greater than at the end of 1948.

The average net mill realization per barrel of portland cement reached $2.30—an increase of 12 cents above the average 1948 price. Other hydraulic cements, as a group, reported a gain of 19 cents a barrel to $2.48.

The long-term trend, as indicated by the moving 12-month total of production of finished portland cement in the Bureau of Mines Monthly Cement Reports, indicated a leveling-off stage, but at a slightly higher plane than in 1948.

Monthly production during 1949 amounted to 15.3 million barrels in January, declined slightly in February, increased gradually to May, and alternately declined and increased for the next 4 months to a high of 19.2 million barrels in September. From this point onward production declined to a year-end low of 17.0 million barrels. The monthly average for the year exceeded 17 million barrels.

Monthly shipments from mills in 1949 exceeded those for 1948 in only 5 months and reached a high in August 1949 compared to a high in June in the previous year. Shipments amounted to 8.8 million barrels in January, increased steadily to 20.7 million barrels in June, decreased in July, and reached the maximum of 23.6 million barrels in August, from which point the shipments decreased gradually to a year-end figure of 11.6 million barrels.

Without exception, stocks for each month of 1949 exceeded those for 1948. Finished cement on hand at the end of January 1949 amounted to 17.6 million barrels, and the maximum reached during the year totaled 23.1 million barrels in March. The low for the year was in October, at which time 8.6 million barrels were in stock.

Consumption of portland cement in 1949, as indicated in figure 1, shows that the Middle States is the largest consuming area.

TABLE 1.—Salient statistics of the cement industry in the United States, 1945–49 [1]

	1945	1946	1947	1948	1949
Production:					
Portland........barrels..	102,804,884	164,064,188	186,519,347	205,448,263	209,727,417
Masonry, natural, and puzzolan (slag-lime)........barrels..	1,483,763	2,474,674	2,951,098	3,440,248	3,185,229

World production (estimated)........do....	291,312,000	425,898,000	498,580,000	583,082,000	652,585,000

[1] Figures include Puerto Rico and Hawaii.
[2] Value received f. o. b. mill, excluding cost of containers.
[3] Revised figure.
[4] 198,723 barrels, valued at $839,916, shipped under the U. S. Army Civilian Supply Program, is excluded from exports shown but deducted from apparent consumption.
[5] Shipments from domestic mills minus net exports.

States in the regions shown in figure 1 are as follows: Northeastern—Connecticut, Delaware, District of Columbia, Maine, Maryland, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, and Vermont; Southern—Alabama, Arkansas, Florida, Georgia, Kentucky, Louisiana, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, Virginia, and West Virginia; Middle—Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin; Rocky Mountain—Arizona, Colorado, Idaho, Montana, Nevada, New Mexico, Utah, and Wyoming; Pacific—California, Oregon, and Washington.

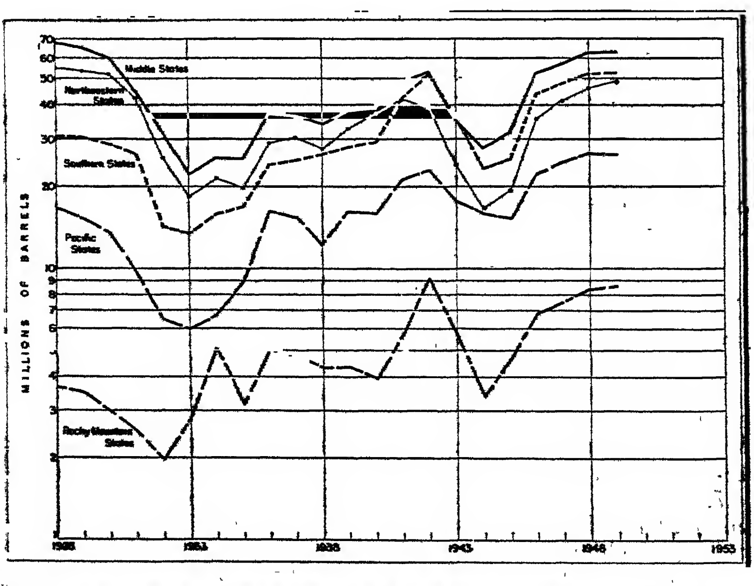

FIGURE 1.—Trends in indicated consumption of portland cement in continental United States, 1928–49, by regions.

In spite of the coal strike during part of the year, shortages of cement that developed were largely localized; and, in general, the supply situation was not critical. The program of rehabilitation and expansion of cement plants that began after World War II continued in 1949. A dry-process plant of the Arizona Portland Cement Co., Los Angeles, Calif., was put into operation at Rillito, Ariz.—the first in that State.[1] Progress has been made on construction of the Corpus Christi, Tex., plant of the Halliburton Portland Cement Co., and it was planned to begin operating by the end of 1949.[2] The possibility of building a cement plant in North Carolina, at present a non-cement-producing State, is being investigated by the State Portland Cement Commission. In a report to the Governor it was recommended that exploratory studies of raw materials be made, particularly around Castle Hayne, and in the general areas of known limestone deposits.[3] Small-scale production of cement has been accomplished in the laboratories of North Carolina State College, using native raw materials.[4] The possibility of establishing a cement plant in North Dakota, also a non-cement-producing State, was investigated during the year.[5] Preliminary research has indicated that there is enough raw material near Colgrove Butte, N. Dak., with which to operate a cement plant.[6]

Many companies improved existing installations during the year. Such improvements included the addition of new kilns, coolers, slurry tanks, and other equipment necessary to maintain or increase production. The Portland Point, N. Y., plant of the Pennsylvania-Dixie Cement Corp., and the Kenova, W. Va., plant of the Green Bag Cement Co. of West Virginia were inactive in 1949.

The uncertainties in cement-industry pricing practice created by the United States Supreme Court decision of April 26, 1948, remained during 1949. The consensus of the industry appears to be that delivered pricing is defensible where no collusion exists but that f. o. b. plant pricing is more certain to be acceptable to the Federal Trade Commission. The basing-point problem was given a great deal of consideration by Congress[7] and by the press[8] during the year.

PRODUCTION, SHIPMENTS, AND STOCKS

PORTLAND CEMENT

Portland cement, which constituted 99 percent of the entire output of hydraulic cements in 1949, was manufactured and shipped from 150 plants in 36 States and Puerto Rico. One new plant in Arizona began operating in December 1949.

In 1949 production was greater in 12 of the 19 districts than in 1948. The changes from 1948 figures ranged from a decrease of 10 percent in the Puerto Rican district to an increase of 19 percent in the Virginia-Georgia-Florida-Louisiana-South Carolina district. Quantitywise, the Eastern Pennsylvania-Maryland district led with an output of 33,799,369 barrels followed by California, which reported the production of 23,218,356 barrels. Other districts producing more than 10 million barrels in 1949 were: New York-Maine, Ohio, Michigan, Indiana-Kentucky-Wisconsin, and Texas. These seven districts supplied 58 percent of the total output.

Shipments from districts in 1949 were greater in nine districts than in 1948. The percentage changes ranged from a decrease of 12 for the Tennessee district to an increase of 19 for the Virginia-Georgia-Florida-Louisiana-South Carolina district. An 11-percent decrease was recorded in the Puerto Rican district.

Stocks of finished cement were 33 percent greater on December 31, 1949, than on the same date in 1948. Without exception, all districts showed increases in stocks at the year end over the preceding year, and these increases ranged from 2 percent in the Michigan, Western Missouri-Nebraska-Oklahoma-Arkansas, and California districts to 119 percent in the Alabama district. The trend of month-end stocks of clinker in 1949 followed essentially the same pattern as in 1948, when the peak was reached in March and the low developed in November.

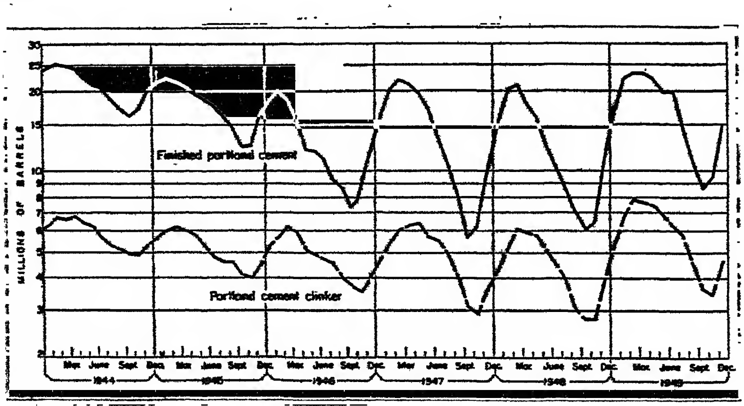

FIGURE 2.—Trends in end-of-month stocks of finished cement and portland-cement clinker, 1944-49.

NATURAL, MASONRY (NATURAL), AND PUZZOLAN CEMENTS

Hydraulic cements, other than portland, were produced in 9 plants in 1949. Output, shipments, and stocks during the year were, respectively, 7, 4, and 23 percent less than in 1948. Producers reported the consumption of 41,783 short tons of coal and 224,434,000 cubic feet of gas (equivalent to approximately 4,694 short tons of coal). Statistics for the 5-year period 1945–49 are shown in the following table.

TABLE 5.—Natural, masonry (natural), and puzzolan (slag-lime) cements produced, shipped, and in stock at mills in the United States, 1945–49

Year	Production		Shipments		Stocks on Dec. 31
	Active plants	Barrels (376 pounds)	Barrels (376 pounds)	Value	Barrels (376 pounds)
1945	9	1,483,763	1,479,513	$2,093,848	170,324
1946	9	2,474,674	2,533,106	4,155,171	112,031

1948	9	3,440,248	3,375,135	7,734,289	[1] 209,901
1949	9	3,185,229	3,233,525	8,006,361	161,605

[1] Revised figure.

TYPES OF CEMENT

A breakdown of the total production of portland cement by various types for the 1945–49 period is shown in the accompanying table. The output of five and shipments of four types of portland cement in 1949 increased over the quantities reported in 1948. Production of sulfate-resisting (type V), oil-well, and portland-puzzolan decreased, and shipments of low-heat (type IV), sulfate-resisting (type V), oil-well, and portland-puzzolan declined. The continued increase in the production of white and air-entrained cement is noteworthy.

Prepared Masonry Mortars.—Production of these mixed materials in 1949 was reported by 98 plants and amounted to 9,259,239 barrels. Shipments totaled 9,007,758 barrels valued at $24,921,761—an average

of $2.77 per barrel. These data are not included in the statistical tabulations in this chapter, but the portland cement used in manufacturing these mixtures is included.

TABLE 6.—Portland cement produced and shipped in the United States,[1] 1945–49, by types

Type and year	Active plants	Production (barrels)	Shipments		
			Barrels	Value	
				Total	Average
General use and moderate heat (types I and II):					
1945	145	89,922,894	93,379,480	$148,653,647	$1.59

CAPACITY OF PLANTS

The total estimated annual capacity of all portland-cement plants in 1949, as reported to the Bureau of Mines by producers, increased 2 percent over that reported in 1948.

The overall rate of operation in 1949 was at 81 percent of the total capacity—the same rate as in 1948. As indicated in the following table, the percentage of capacity utilized gained in 10 and decreased in 8 districts. There was no change in one district. In the continental United States the increases in percentage points ranged from 2 (in 4 districts) to 16 in the Virginia-Georgia-Florida-Louisiana-South Carolina district. A decrease of 36 points was recorded in the Puerto Rican district. The percentage of capacity utilized in each month of 1949 was slightly higher for the first 4 months than in 1948, but beginning in June the industry operated at a lower level. As in 1948, the peak was reached in September, with a decline at year end.

TABLE 7.—Portland-cement-manufacturing capacity of the United States, 1948–49, by districts

District	Estimated capacity (barrels)		Percent of capacity utilized	
	1948	1949	1948	1949
Eastern Pennsylvania, Maryland	38,943,325	38,403,325	86.3	88.0
New York, Maine	17,561,640	17,398,048	76.9	79.5
Ohio	12,952,515	12,952,515	77.5	79.6
Western Pennsylvania, West Virginia	13,961,300	14,961,300	64.0	59.7
Michigan	14,200,000	15,394,776	80.4	82.9

June	89	87	80	83	December	84	78	84	82

The total capacity of wet-process plants, as indicated in the accompanying table, continued to increase. Dry-process plants, whose capacity declined slightly in 1948, increased to virtually the same figure as in 1947. The percentage of cement produced by wet-process plants in 1949 increased slightly over that for 1948 and declined for dry-process operations.

TABLE 9.—Capacity of portland-cement plants in the United States,[1] 1947–49, by processes

Process	Capacity						Percent of capacity utilized			Percent of total finished cement produced		
	Thousands of barrels			Percent of total								
	1947	1948	1949	1947	1948	1949	1947	1948	1949	1947	1948	1949

[1] Includes Puerto Rico and Hawaii.

A grouping of the cement plants based on their annual capacity is shown in the following table. Substantial gains were recorded in the 2,000,000- to 3,000,000-barrel-capacity group, whereas the number of plants in the 1,000,000- to 2,000,000-barrel-capacity group declined. There were no changes in two remaining groups.

Number of portland-cement plants in the United States (including Puerto Rico) by size groups, in 1949

Estimated annual capacity, barrels:	*Number of plants*
Less than 1,000,000	26
1,000,000 to 2,000,000	87
2,000,000 to 3,000,000	28
3,000,000 to 10,000,000	11
Total	152

CLINKER PRODUCTION

The output of clinker, the intermediate product between raw materials and the finished cement, was 2 percent greater in 1949 than in 1948. Peak production was reached in May, while stocks reached their greatest accumulation in March. Stocks of clinker on December 31, 1949, were 21 percent greater than those reported for the year-end 1948.

TABLE 10.—Production and stocks of portland-cement clinker at mills in the United States in 1949, by months and districts, in thousands of barrels

District	January	February	March	April	May	June	July	August	September	October	November	December

[1] Including Puerto Rico.
[2] Compiled from monthly estimates of producers.
[3] Revised figures.
[4] Preliminary figures.

RAW MATERIALS

"Limestone and clay or shale" have been the predominant constituents in portland cement for the past 40 years. In 1949, 72 percent of the output was made from this combination compared with 71 percent in 1948. "Cement rock and pure limestone" furnished 22 percent in 1949, whereas the combination of "blast-furnace slag and limestone" supplied 5 percent of the output. As in the past years, "marl and clay" supplied a minor part of the raw materials utilized by the cement industry, accounting for 2 percent of the output.

TABLE 12.—Production and percentage of total output of portland cement in the United States,[1] 1901–14, 1926, 1929, 1933, 1935, and 1941–49, according to raw materials

Year	Cement rock and pure limestone		Limestone and clay or shale[2]		Marl and clay		Blast-furnace slag and limestone	
	Barrels	Percent	Barrels	Percent	Barrels	Percent	Barrels	Percent
1901	8,503,500	66.9	2,042,209	16.1	2,001,260	15.7	164,316	1.3

[1] Includes Puerto Rico and Hawaii, 1941–49.
[2] Includes output of 2 plants using oystershells and clay in 1926; 3 plants in 1929, 1933, and 1935; 4 plants in 1941–45; and 5 plants in 1946–49.

The tonnages of raw materials (exclusive of fuel and explosives) required for the production of portland cement in 1947–49 are given in the following table. Limestone, cement rock, and clay and shale constitute 94 percent of the total materials consumed in 1949. Except for cement rock and blast-furnace slag, all types of materials consumed during the year gained over 1948.

TABLE 13.—Raw materials used in producing portland cement in the United States,[1] 1947–49

Raw material	1947	1948	1949
	Short tons	*Short tons*	*Short tons*
Cement rock	11,728,062	13,046,856	12,628,494
Limestone (including oystershells)	40,034,322	43,489,837	44,968,739
Marl	563,148	601,716	722,606
Clay and shale [2]	5,373,591	6,440,584	6,698,408
Blast-furnace slag	864,617	896,474	847,375
Gypsum	1,445,622	1,507,876	1,543,198
Sand and sandstone (including silica and quartz)	821,017	723,769	724,624
Iron materials [3]	257,048	318,106	346,542
Miscellaneous [4]	147,056	133,716	140,999
Total	61,234,483	67,158,934	68,620,985
	Pounds	*Pounds*	*Pounds*
Average total weight required per barrel (376 pounds) of finished cement	657	654	654

[1] Including Puerto Rico and Hawaii.
[2] Includes bentonite, diatomaceous shale, and fuller's earth.
[3] Includes iron ore, pyrite cinders and ore, and mill scale.
[4] Includes diatomite, fluorspar, pumicite, flue dust, pitch, red mud and rock, hydrated lime, tufa, cinders, calcium chloride, sludge, grinding aids, and air-entraining compounds.

FUEL AND POWER

Of all the fuels used in the manufacture of portland cement (coal, fuel oil, natural gas, and byproduct gas), only natural gas showed an increase in the amount consumed during 1949. The percentage changes in consumption compared with 1948 are: Coal, 7-percent decrease; fuel oil, 2-percent decrease; natural gas, 17-percent increase; and byproduct gas, 86-percent decrease. Average monthly consumption of these fuels in 1949 compared to 1948 (1948 averages in parentheses) was: Coal, 665,630 (712,804) short tons; fuel oil, 382,217 (388,196) barrels; natural gas, 7,043,433 (6,011,568) thousand cubic feet; and byproduct gas, 14,007 (97,865) thousand cubic feet.

The number of plants using electric energy, the kilowatt-hours generated and purchased, and the average electric energy used per barrel of cement compared with 1948 figures are shown in an accompanying table. The percentage of electricity generated declined slightly, and the quantity purchased increased.

TABLE 14.—Finished portland cement produced and fuel consumed by the portland-cement industry in the United States,[1] 1948–49, by processes

Process	Finished cement produced			Fuel consumed [2]		
	Plants	Barrels of 376 pounds	Percent of total	Coal (short tons)	Oil (barrels of 42 gallons)	Natural gas (M cubic feet)
1948						
Wet	89	111,152,861	54.1	4,182,633	2,828,993	50,868,082
Dry	61	94,295,402	45.9	4,371,017	1,829,363	[3] 22,445,110
Total	150	205,448,263	100.0	[4] 8,553,650	4,658,356	[3] 73,313,192
1949						
Wet	88	116,522,681	55.6	3,830,313	3,203,950	61,783,635

EMPLOYMENT AND PRODUCTIVITY

Trends in employment and output per man in the cement industry in 1945–46 are shown in the tables following. Supplemental data for 1945–46 and corresponding data for earlier years were published in Minerals Yearbook, 1947, pp. 220–221.

TABLE 17.—Employment in the portland-cement industry, finished cement produced at mills included in study, and average output per man in the United States,[1] 1945–46, by districts

District	Employment					Production			Percent of industry represented[2]
	Average number of men	Time employed				Finished portland cement (barrels)	Average per man (barrels)		
		Average number of days	Total man-shifts	Man-hours			Per shift	Per hour	
				Average per man per day	Total				
1945									
Eastern Pennsylvania and Maryland	3,213	260	835,619	8.1	6,760,771	14,511,861	17.37	2.15	100.0

[1] Exclusive of Puerto Rico and Hawaii.
[2] Calculated for each year by dividing quantity of finished cement produced at mills included in study by total production.

TRANSPORTATION

The quantity and proportion of cement shipped by each of the major methods of transportation for 1947–49 are listed in an accompanying table. The proportions shipped by truck in 1949 increased somewhat, whereas rail shipments declined, and the percentage carried by boat remained virtually the same.

TABLE 20.—Shipments of portland cement from mills in the United States,[1] 1947–49, in bulk and in containers, by types of carriers

[Barrels of 376 pounds]

Type of carrier	In bulk		In containers				Total shipments	
	Barrels	Percent	Bags: Paper (barrels)	Bags: Cloth (barrels)	Other containers[2] (barrels)	Total (barrels)	Barrels	Percent

[1] Includes Puerto Rico.
[2] Includes steel drums and iron and wood barrels.
[3] Includes cement used at mills by producers as follows—1947: 813,830 barrels; 1948: 646,420 barrels; 1949: 643,174 barrels.
[4] Less than 0.05 percent.

CONSUMPTION

The following tabulation shows that the indicated consumption of portland cement in 1949 increased in 30 States and the District of Columbia. Variation of percentages for the various States compared with 1948 ranges from a decrease of 29 for Arizona to an increase of 49 for Delaware. California, New York, Texas, Pennsylvania, Illinois, Ohio, and Michigan in that order were the largest consumers of cement in 1949. These 7 States accounted for 45 percent of the total consumption, while the 14 non-cement-producing States, including the District of Columbia, accounted for 12 percent of the total consumption.

TABLE 21.—Destination of shipments of finished portland cement from mills in the United States, 1947–49, by States

Destination	1947 (barrels)	1948 (barrels)	1949	
			Barrels	Change from 1948, percent
Continental:				
Alabama	2,930,108	3,178,143	2,910,444	−8.4

Total continental United States	179,253,344	196,193,667	200,248,023	+2.1
Outside continental United States [4]	8,238,525	8,110,995	5,832,302	−28.1
Total shipped from cement plants	187,491,869	204,304,662	206,080,325	+.9

[1] Non-cement-producing State.
[2] Included with cement-producing States in December 1949.
[3] South Carolina was a non-cement-producing State in 1947 and 1948 only.
[4] Direct shipments by producers to foreign countries and to noncontiguous Territories (Alaska, Hawaii, Puerto Rico, etc.), including distribution from Puerto Rican mills.

[1] Shipments by producers to foreign countries and to noncontiguous Territories of the United States (Alaska, Hawaii, Puerto Rico, etc.), including distribution from Puerto Rican mills.

LOCAL SUPPLY

The surplus or deficiency in the quantity of cement locally available is indicated in the following table. The comparison is based on shipments from mills and on consumption as shown by State receipts of mill shipments. The 1949 deficiencies occurred in one State and six districts.

The total surplus of producing States in 1949 was distributed as follows: 23,451,774 barrels to non-cement-producing States, Alaska, and Hawaii; 3,666,101 barrels to destinations outside continental United States (excluding local consumption of Puerto Rican production); and 52 barrels to unspecified destinations.

TABLE 23.—Estimated surplus or deficiency in local supply of portland cement in cement-producing States, 1948–49, in barrels

[1] Arizona first began shipping in December 1949.
[2] South Carolina first began shipping in January 1949.

PRICES

The average net mill realization of all portland cement shipped from mills in 1949 advanced to $2.30 per barrel from $2.18 in 1948. The average net mill realization in each quarter of 1949 was: First, $2.33; second, $2.30; third, $2.28; and fourth, $2.30.

The composite wholesale price of portland cement, f. o. b. destination, according to the Bureau of Labor Statistics index (1926=100), was 133.8 in 1949, whereas in 1948 it was 130.4.

Average mill value per barrel, in bulk, of portland cement in the United States,[1] 1944–49

1944	$1.59	1947	$1.90
1945	1.63	1948	2.18
1946	1.72	1949	2.30

[1] Includes Puerto Rico and Hawaii.

FOREIGN TRADE [9]

Imports.—Imports of hydraulic cement decreased sharply in 1949, amounting to 109,821 barrels compared with 282,752 barrels (revised figure) in 1948, and for the most part representing purchases from Belgium-Luxembourg, Germany, Mexico, and the United Kingdom. Imports of all hydraulic cement, except white, nonstaining, and other special cement, for 1947–49 are listed by country of origin in the second table following. Imports of white, nonstaining cement in 1949 amounted to 35 barrels valued at $142.

[1] Excludes "white, nonstaining, and other special cement."

Exports.—Exports of cement in 1949 declined slightly to 4,561,899 barrels valued at $15,960,954. As indicated in the following table, shipments to North America and to South America amounted to 93 percent of the total. The largest purchasers were Canada, Cuba, Mexico, and Venezuela.

Shipments of hydraulic cement to noncontiguous Territories of the United States for the 1947–49 period are shown in an accompanying

[9] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

table. Shipments to Puerto Rico and the Virgin Islands increased over the previous year's figures, while shipments to American Samoa, Guam, and Wake Island decreased.

TECHNOLOGY

The question of free lime in cement is one that has been discussed for many years. According to a recent report,[10] tricalcium silicate, an important compound in clinker, decomposes below 1,250° C. to form beta-Ca_2SiO_4 and secondary free lime. The report states further that these products, formed by a reaction in the solid state, are much finer in grain size (below 1 micron) than the same compounds primarily formed under the action of polyeutectic melts, especially in the clinkering process.

According to a recent article,[11] the belief that a direct relationship exists between the amount of free lime in cement and irregularity in volume changes is incorrect. Such irregularity is not caused by free lime but by other factors. The author states further that determination of free lime in cements by the Emley and analogous methods was found to be unsatisfactory. Instead, the Baikov method is recommended.

The possibility of using natural anhydrite as a substitute for gypsum wholly or in part in the manufacture of portland cement has been advanced. Some attempts have been made previously to substitute natural anhydrite for gypsum, but not on a commercial scale. In making the tests presented in a recent article,[12] seven clinkers were ground with varying percentages of gypsum, and tests made to determine the optimum amount of SO_3 for each clinker. The clinkers were then ground with this optimum amount of SO_3 in the form of mixtures of gypsum and natural anhydrite and the tests repeated. According to the article, a comparison of the results obtained with gypsum alone and with blends of gypsum and natural anhydrite indicated that, with one clinker, 25 percent and, with the others, 60 to 75 percent of the gypsum could be replaced by natural anhydrite without adversely affecting the properties of the cement.

A waterproofing admixture called "Zilicon," which is added directly to portland-cement concrete mixtures, has been announced. Its purpose is to waterproof concrete and cement mortars by providing water repellency. This integral admixture is designed for concrete, stucco, cement and brick mortar, cement plaster coat, etc.[13]

Another development of interest to the industry is the "Aerocem" cement spraying process, for applying ordinary or special mixtures of cement to almost any kind of surface. The Aerocem equipment consists of a pressure pot, a pneumatic aerator, air and fluid lines, and the Aerocem gun.[14]

Four patents relating to cement and cement concrete have been released. One, United States Patent 2,427,683, applies to slow-setting cements for use in cementing high-temperature deep wells. Adding 0.05–0.75 pound of carboxymethylcellulose or its salts per 100 pounds of dry cement retards the setting time at about 82°–104.4° by 3–10 hours. The addition of 0.05–0.50 pound of hydroxyethylcellulose per 100 pounds of dry cement retards the setting time similarly but

[14] Cement Lime and Gravel, vol. 23, No. 11, May 1949, p. 372.

in the 60°–82° temperature range.[15] United States Patent 2,466,601 describes a rotary kiln and other apparatus for burning cement.[16] United States Patent 2,458,039 describes a procedure for improving the strength and resistance of portland-cement concrete to freezing and thawing by substituting water-cooled slag for about 20 percent of the cement.[17] United States Patent 2,489,211, dated November 22, 1949, covers a countercyclone "clinkerer." [18]

During 1949 the American Society for Testing Materials, acting through its Committee C–1 on Cement, revised some of the standard specifications and adopted new tentative specifications. Revisions were proposed for the following specifications: (1) Standard Specification for Portland Cement (C 150–47), (2) Standard Method of Test for Autoclave Expansion of Portland Cement (C 151–43), (3) Standard Specifications for Masonry Cement (C 91–48), and (4) Standard Method of Test for Fineness of Portland Cement by the Turbidimeter (C 115–42). Tentative Method of Test for Air Content of Air-Entraining Portland-Cement Mortar (C 185–47) was retained without revision. The following methods and specifications were tentatively adopted: (1) Tentative Method of Test for Sodium Oxide and Potassium Oxide in Portland Cement by Flame Photometry (C — - 49 T), (2) Tentative Specifications for Flow Table for Use in Tests of Hydraulic Cement (C — - 49 T), and (3) Proposed revised Tentative Specifications for Natural Cement (C 10 - — T).[19]

It has also been announced that A. S. T. M. Committee C–1 on Cement has declared "N-Tair" acceptable as an addition to the cements covered in tentative specifications C175 and C205. N-Tair consists substantially of a sodium resinate produced from pine-wood stumps from which the bulk of the petroleum-naphtha-soluble resin acids has been removed.[20]

Another air-entraining agent, known as "Ertrane C" for use in portland cement, has been developed. It is stated to be composed essentially of sodium soap of a partially heat-treated and polymerized fatty acid-resin mixture.[21]

Other investigations and results of research on portland cement were released during 1949. These included reports on cement hydration and related problems,[22] the determination of aluminum oxide in portland cement,[23] studies of nonevaporable water content of hardened portland-cement paste,[24] and the results of research on concrete exposed to sulfate soils.[25]

Victoria	127,971	133,407	152,763	194,777	195,488	
New Zealand	229,200	237,600	229,900	219,409	247,205	254,039
Total [14]	54,855,000	49,684,000	72,638,000	85,034,000	99,446,000	111,300,000

[1] In addition to countries listed, hydraulic cement is produced in Albania, Madagascar, Queensland, South Australia, and Tasmania, but data are not available.
[2] Data not available; estimate by senior author of chapter included in total.
[3] Estimate.
[4] Data represent Trianon Hungary after October 1944.
[5] January to June, inclusive.
[6] June to December, inclusive.
[7] April to December, inclusive.
[8] Data represent area designated as Free China during the period of Japanese occupation, and Manchuria.
[9] Manchuria only.
[10] Beginning September 1947, excludes Pakistan.
[11] Production in Government-operated plants only.
[12] Fiscal year ended Mar. 20 of year following that stated.
[13] Included in India.
[14] Estimated by senior author of chapter; excludes estimates for countries listed in footnote 1.

Chromium

By Robert H. Ridgway

GENERAL SUMMARY

SUPPLIES of chromite for United States use in 1949, virtually all obtained from foreign sources, continued to exceed consumption in all grades despite a virtual embargo on shipments from the U. S. S. R. As a result of this excess, industry stocks of all grades increased during the year, and substantial tonnages were available for the national stockpile. Chemical-grade chromite was added to the stockpiling list in 1949, making the list complete with regard to the various grades of chromite. The world sources of chromite in 1949 followed the usual pattern, although there were changes in the relative position of the supplying countries. Turkey was the largest supplier of United States chromite during the year, having shipped a record total of 275,805 short tons, of which most was high-grade metallurgical ore. The Republic of the Philippines was a close second, although most of its shipments were refractory material of the Masinloc type; substantial tonnages of metallurgical ore came from the Philippines, although this was of a somewhat lower grade than the Turkish. The Union of South Africa, the third largest supplier, was the source of by far the largest supply of chemical-grade material; in fact, the Union is considered the sole source of acceptable chemical chromite. Such ore is commonly known as Transvaal Grade B Friable. The Soviet Union, which supplied nearly 400,000 tons of high-grade material in 1948, supplied only 107,131 short tons in 1949, much of which was received early in the year. This was similar to the Russians' action with respect to manganese ore and was taken without official notice of the Soviet Government but was announced merely by the shippers, who indicated that only token shipments would be made in the future. Cuba continued to ship substantial tonnages of refractory ore and some metallurgical, although considerably less of both than in the previous year; higher production costs of refractory chromite, together with increased competition of Philippine material, caused much of the decline in production during 1949.

The total new supply of chromite in 1949, although exceeding industry requirements, was far below the all-time high of 1948. The rather high industry inventories accumulated in 1949 resulted in rejection of offers of certain grades, and receipts were below what might have been obtained under maximum market demand. Quoted prices dropped off during 1949, and many deliveries were at prices considerably below these; transactions were reported at $15 per long ton, f. o. b. United States ports, for some of the grades at the close of the year.

Consumers' stocks totaled 756,995 short tons on December 31, 1949. Of this, 325,881 tons were metallurgical, 303,110 tons were refractory, and 128,004 tons were chemical grade. Stocks of these grades December 31, 1948, were 256,770 tons, 236,724 tons, and 108,997 tons, respectively.

Salient statistics of chromite in the United States, 1945–49, in short tons

		1946		1948	1949
Total supply	928,738	761,498	1,107,128	1,545,744	1,204,344
Imports for consumption	914,765	757,391	1,106,180	1,542,125	1,203,911
Domestic production	13,973	4,107	948	3,619	433
Consumption by industry	808,120	734,759	833,357	875,033	672,773
Exports	12,366	2,158	3,435	2,894	2,382

DOMESTIC PRODUCTION

Domestic production of chromite in 1949 was the lowest since 1936. This output, 433 tons, came from one mine in Butte County, two in Del Norte County, and one in Tehama County—all in California. R. F. Helmke, operating the Lambert mine near Magalia, Butte County, shipped 162 tons; Sam J. Wilson, operating the Tyson Chrome mine, Del Norte County, shipped 160 tons; Eugene Brown shipped 54 tons from the High Plateau mine, Del Norte County; and Harry Moore shipped 57 tons from the Tedoc and Red Mountain mines in Tehama County. All of the chromite produced in 1949 is believed to have been used for metallurgical purposes.

The Pacific Northwest Alloys, Inc. (formerly the Chromium Mine & Smelting Corp., Ltd.), continued its experiments at Mead, Wash., to develop a process for producing exothermic chromium alloys from domestic materials.

Chromite production (shipments) in the United States, 1945–49, by States, in short tons, and number of producers in 1949

State	1945	1946	1947	1948	1949		
					Number of producers	Short tons	Value
California	9,607	[1] 4,107	948	274	4	433	$11,662
Oregon	4,366			3,345			
Total	13,973	4,107	948	3,619	4	433	11,662

[1] Bureau of Mines not at liberty to publish separate State totals for California and Oregon in 1946.

Chromite shipped from mines in the United States, 1880–1949 [1]

Year	Short tons	Year	Short tons	Year	Short tons	Year	Short tons
Before 1880	224,000	1897–99	--------	1917	48,972	1935	577

1886	2,240	1906	120	1924	323	1942	112,876
1887	3,360	1907	325	1925	121	1943	160,120
1888	1,680	1908	402	1926	158	1944	45,629
1889	2,240	1909	670	1927	225	1945	13,973
1890	4,031	1910	230	1928	739	1946	4,107
1891	1,537	1911	134	1929	301	1947	948
1892	1,680	1912	225	1930	90	1948	3,619
1893	1,624	1913	286	1931	300	1949	433
1894	4,122	1914	662	1932	174		
1895	1,949	1915	3,675	1933	944	Total	848,152
1896	880	1916	52,679	1934	413		

[1] Production of chromite before 1880 was "about 200,000 long tons" (224,000 short tons), all from Maryland and Pennsylvania, according to Mineral Resources, 1908, pt. 1, p. 760. Most of the figures for 1880–95 represent conversions to short tons from rounded long tons.

CONSUMPTION AND USES

Consumption of chromite during 1949 decreased 23 percent from 1948. This decrease resulted partly from a 12-percent drop in steel-ingot production, which resulted in lower requirements for refractories to rebuild open-hearth furnaces. The drop in consumption of metallurgical chromite (27 percent) resulted from decreases in demand for alloy steels (31 percent) that were much more evident than the decline in the over-all steel-ingot rate.

As to the various consuming industries, metallurgical consumption was off 27 percent, refractory 18 percent, and chemical 24 percent for 1949. Metallurgical and chemical consumption was less than in any war or postwar year, but refractory, which was less than 1947 or 1948, exceeded the three previous years. The percentages of metallurgical, refractory, and chemical ores used in 1949 were 43, 40, and 17 percent, only slightly changed from the comparable 1948 percentages of 45, 38, and 17 percent, respectively.

The average chromic oxide content of the various grades used in 1949 was slightly lower than in the previous year, averaging 41.3 percent Cr_2O_3, compared with 42.7 percent in 1948. In general, the metallurgical material has the highest Cr_2O_3 content, with chemical slightly lower and refractory material the lowest.

Consumption of chromite and tenor of ore used by primary consumer groups in the United States, 1941–49, in short tons

Year	Metallurgical		Refractory		Chemical		Total	
	Gross weight (short tons)	Average tenor (percent Cr_2O_3)	Gross weight (short tons)	Average tenor (percent Cr_2O_3)	Gross weight (short tons)	Average tenor (percent Cr_2O_3)	Gross weight (short tons)	Average tenor (percent Cr_2O_3)

Consumption of ferrochromium in the United States in 1949 dropped sharply to 87,764 short tons, compared with 122,753 tons in 1948 and 113,491 tons in 1947. In addition to this ferrochromium, substantial tonnages of chromium metal and chromium in the form of chromium briquets and Chrom-X were used in the manufacture of steels and chromium alloys; some chromite was used direct in the manufacture of stainless steel.

Specifications.—The mineral chromite does not have a fixed chemical composition. It is usually spoken of as $Cr_2O_3 \cdot FeO$ but also contains varying proportions of iron, alumina, magnesia, lime, and silica. These additional elements, although lowering the grade of the material in terms of chromium content, are essential to certain applications, as may be seen from the usual trade specifications outlined below.

For metallurgical use, such as the manufacture of ferrochrome, chromite generally should contain a minimum of 48 percent Cr_2O_3, with a chromium:iron ratio of not less than 3:1. Further, the ore should be hard, and lumpy. Usual specifications call for 6-inch maximum size of piece, with not more than 10 to 15 percent through a ½-inch screen. Silica is undesirable, and combined alumina and magnesia of over 25 percent may be objectionable.

Refractory-grade chromite usually contains about 63 percent combined Cr_2O_3 and Al_2O_3, with 57 percent a common minimum. Iron and silica should be low, usually around 10 and 5 percent, respectively.

Hard lump ore is desirable for making bricks, and ground material is suitable for cement. Magnesia content is around 15 percent.

Chemical-grade chromite should contain a minimum of 45 percent Cr_2O_3. High iron is not harmful within reasonable limits; a common chrome: iron ratio is 1.6 : 1. Silica must be less than 8 percent and sulfur low. Fines and concentrates are often preferred because they disintegrate readily in processing.

Metallurgical Uses.—The main sources of metallurgical chromite for the United States are Turkey, Southern Rhodesia, New Caledonia, Union of South Africa, and the Republic of the Philippines. Much of the chromite used is considerably lower in quality than the standard specified above. The lower grades, however, result in somewhat lower-grade ferrochromium, the alloy most commonly used in adding chromium to steels. In general, ferrochromium is made in two grades—high carbon and low carbon; the lower carbon is essential in the manufacture of certain grades of steel, especially stainless. Except for the chromite used direct in steel production, all the metallurgical grades are consumed in electric furnaces in the manufacture of chromium ferro-alloys. Steels that depend on chromium include some structural steels, tool steels, high-speed steels, bearing steels, and stainless steels.

Refractory Uses.—Chromite refractories are valuable in lining steel-making furnaces because of their peculiar property of being resistant to both acid and basic slags. Because of this neutral chemical characteristic, these refractories can be built into furnaces between basic bottoms and acid roofs. Prepared chromite is also used in a crushed condition to repair furnace linings. A refractory composed of chromite and magnesite also is used extensively for furnace linings.

Chemical Uses.—The largest use for chemical chromite is in the manufacture of pigments and tanning of leather, and surface treatment of metals represents the next most important use. In all chemical uses, sodium bichromate is the primary chemical produced from chromite. Chromium metal, although a metallurgical material, is also produced from chemical-grade chromite with sodium bichromate as the intermediate product. The metal is finding new substantial markets in the production of high-temperature alloys, such as are used in engines for jet aircraft, and for antifriction purposes, where it is deposited by electrolytic methods. The third largest use mentioned (surface treatment of metals) is again a use for sodium bichromate in cleansing, pickling, red dip for brass, and galvanizing.

PRICES

Prices on imported chromite are quoted on a long-ton basis f. o. b. cars, Atlantic ports, plus ocean freight differentials for delivery to the west coast. Domestic shipments are sold f. o. b. nearest rail point. Quoted prices shown in the accompanying table from the magazine Steel reflect the continued high level of supply during 1949 through lower prices.

Price quotations for various grades of chromite in 1949

[Steel]

Source	Cr_2O_3 (percent)	Cr : Fe ratio	Prices per long ton [1]

[1] Gross ton f. o. b. cars, New York, Philadelphia, Baltimore, Charleston, S. C., plus ocean freight differential for delivery to Portland, Oreg., or Tacoma, Wash.
[2] Lump.

Prices of ferrochromium remained steady during 1949 at 20.5 cents per pound of contained chromium for high carbon and 28.75 cents per pound for low carbon (0.06 percent carbon). Chromium metal (97 percent Cr min., 0.50 percent C max.) remained at $1.03 per pound of contained chromium during the year. The prices for metal and alloys given here are for bulk, carload lots. Basic chrome brick prices were unchanged during 1949 at $69 per net ton, f. o. b. Baltimore, Md., or Chester, Pa.

FOREIGN TRADE [1]

Imports of chromite in 1949 decreased 22 percent from 1948 and amounted to 1,203,911 short tons containing 533,591 tons of Cr_2O_3; the value was $24,189,442, a drop of 27 percent. According to the Bureau of the Census, chemical imports constituted 18 percent of total imports, metallurgical 56 percent, and refractory 26 percent.

Imports of ferrochromium in 1949 totaled 7,491 short tons containing 4,012 tons of Cr and were valued at $1,279,598. Of the imports, 7,367 tons originated in Canada and 124 tons in Japan.

Exports of ferrochromium totaled 2,200 short tons, of which Italy and Austria were the largest recipients. Chromic acid exports totaled 1,404,227 pounds valued at $422,471. Exports of chromite were 2,382 short tons valued at $74,034.

[1] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Chromite imported for consumption in the United States, by countries and by grades, 1948–49

WORLD REVIEW

Cyprus.—The Cyprus Chrome Co., Ltd., having expanded its operations and installed a gravity concentrator, is reported to have treated 11,394 long tons of ore to produce 5,196 tons of concentrates in 1948. A total of 6,790 long tons of lump ore and concentrates were exported.[2]

Greece.—Although Greece was a rather productive source of chromite during World War II, there has been only small production in recent years. In 1949 a trade agreement to ship small tonnages of chromite to France was reported, and reopening the Tsagli Chrome mine near Volos was planned. This was to be possible as a result of rebuilding the wharves at Volos and rehabilitating the railway.[3]

India.—Chromite occurs in the Zhob Valley, Baluchistan; Singhbhum district, Bihar; Keonjhar, Oressa; and Hasan, Mysore.[4]

Exports of chromite from India amounted to only 5,002 long tons in 1948, compared with 8,633 tons in 1947. Of the 1948 exports, 1,180 tons went to Belgium, 500 tons to Egypt, 2,500 tons to Norway, and 822 tons to Sweden.

Madagascar.—The Government newspaper "Informations de Madagascar" on July 19, 1949, described the discovery of a chromite deposit along the Ivoloina River, near Tamatave, in the district of Tamatave, on the east coast of Madagascar. The deposit was reported to be large, and it was stated that a company called Le Chrome Malgache has been formed to develop the property. A small shipment of 300 tons was reported sent to France.

New Caledonia.—In production of chromite, New Caledonia has risen substantially since 1946, and a total of 75,021 metric tons was reported in 1948. Most of this material is high-grade metallurgical ore. It is said [5] that operations are now controlled by the Sté. Caledonienne du Chrome, a combination of the five leading producers.

Philippines.—A lack of demand for chromite in the United States resulted in shut-downs or drastic reductions in production at several of the important mines in the Philippines late in 1949. A stoppage at the Masinloc chromite deposits was reported in December; other chromite properties were completing present contracts.[6]

Sierra Leone.—The most important deposits of chromite in Sierra Leone are the Lago, 6 miles north of Hangsha, 186 rail miles from Freetown. Most of the ore is exported to the United States.[7]

Southern Rhodesia.—Chromite is reported to represent over 10 percent of the total value of Southern Rhodesia's mineral production.[8]

Turkey.—It was reported in 1949 that a trade agreement was reached whereby Turkey would provide Austria with at least 40,000 tons of chromite per year.[9]

A new chromite deposit with an estimated reserve of 300,000 tons was prospected recently at Sori, 15 kilometers from Guleman, Western Anatolia.[10]

Union of South Africa.—Chromite occurs in very large tonnages in the Transvaal, which is one of the largest producing areas in the

Clays

By Robert W. Metcalf and A. M. Linn [1]

GENERAL SUMMARY

CLAY production decreased 7 percent in 1949, and shipments of the principal types of structural clay products also were somewhat smaller than in 1948. All classifications of clay herein discussed decreased, ranging from 4 percent for miscellaneous clays to 17 percent for ball clays.

The demand for common clays and shales (miscellaneous clays) remained heavy, and their use in portland cement increased 4 percent. Common clays and shales comprised nearly all of the clay used in portland and other hydraulic cements and 83 percent of that used for heavy clay products.

Sales of kaolin and ball clay declined 10 and 17 percent, respectively, in 1949, compared with 1948, although use of kaolin in rubber and of ball clay in high-grade tile each was somewhat larger than in 1948.

Salient statistics of the clay industry in the United States, 1948–49

	1948		1949	
	Short tons	Value	Short tons	Value
Domestic clay sold or used by producers:				
Kaolin or china clay	1,568,848	$19,756,738	1,415,537	$19,007,547
Ball clay	298,979	3,342,647	248,883	3,064,439

Other clay	3,687	29,454	3,367	17,287
Total imports	135,941	2,142,070	105,105	1,481,399
Exports:				
Kaolin or china clay	19,074	319,294	21,839	362,615
Fire clay	[illegible]	[illegible]	80,736	766,195
Other clay (including fuller's earth)	[1] 145,293	[1] 3,883,610	142,308	3,666,775
Total exports	266,849	5,138,136	244,883	4,795,585

[1] Revised figure.

After 11 years of constantly increasing output, production of bentonite in 1949 decreased 6 percent compared with 1948, the peak year. The 1949 figure—867,243 tons—still was higher than in any year except 1948. Use as foundry-sand bond fell sharply; rotary

[1] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

drilling mud showed a moderate decrease, but filtering and decolorizing oils (raw and activated earths) were 5 percent greater than in 1948.

Total production of fuller's earth in 1949 decreased moderately, although its use in insecticides and fungicides and as rotary drilling mud showed large gains compared with 1948.

Owing to the coal and steel stoppages, production of fire clay in 1949 declined substantially compared to the previous year. Use in heavy clay products was only slightly less than in 1948.

Price quotations of clay and clay products in 1949, as given in trade journals, generally remained at the same levels as in 1948, except for certain grades of domestic and imported kaolins, which increased moderately.

Imports of kaolin or china clay in 1949 declined to 77,226 short tons, which, except for the war years 1941–45, were the lowest receipts in 50 years. Imports of common blue and ball clays, including Gross Almerode, also decreased sharply in 1949. The average unit value of imports of both kaolin and blue and ball clays dropped more than $1.50 per ton. The source of each of these two types of clay in 1949 was largely United Kingdom, with very small amounts of kaolin from Canada and Czechoslovakia and small quantities of common blue and ball clays from Canada and Germany. Exports of kaolin or china clay in 1949 rose 14 percent compared with 1948, and 88 percent of the total was shipped to Canada. Fire-clay exports, largely also to Canada, decreased 18 percent. Exports of the three classes of clay shown had a wide distribution, reaching all six continents.

CONSUMPTION AND USES

The clay-consumption data shown in the accompanying table for kaolin, ball clay, bentonite, and fuller's earth are comparable with statistics published in Minerals Yearbooks for all previous years. However, the fire-clay and miscellaneous clay data, beginning with 1944, include captive tonnage and therefore are not comparable with earlier years. A discussion of these differences appeared in Minerals Yearbook, 1944 (pp. 1326–1338).

Heavy clay products in 1949 consumed 6 percent less clay than in 1948 and comprised 57 percent of the total clay produced. Clays used in portland and other hydraulic cements amounted to 19 percent of the output of all clays; refractories, 15 percent; paper filler and coating clays, 2 percent; and rotary drilling mud, filtering and decolorizing oils, and pottery, 1 percent each. The remainder was consumed for a large number of miscellaneous purposes.

Although most of the uses of clays declined in tonnage in 1949 compared with the previous year, several gained over 1948. Among those increasing were linoleum, 5 percent; enameling, 6 percent; portland and other hydraulic cements, 4 percent; rubber, 17 percent; and insecticides and fungicides, 45 percent. Important classifications with decreases were refractories, 20 percent; pottery, 17 percent; paper filler and coating, 13 percent; rotary-drilling mud, 10 percent; filtering and decolorizing oils, 7 percent; and heavy clay products, 6 percent.

Clay sold or used by producers in the United States in 1949, by kinds and uses, in short tons

[1] Comprises the following: Mineral oils, 151,353 tons; vegetable oils, 19,806 tons.

CHINA CLAY OR KAOLIN

Domestic production of china clay or kaolin in 1949 declined 10 percent from the record year 1948 to 1,415,537 short tons; it was slightly less than 1947 but higher than in any prior year. The total value decreased only 4 percent and was the highest value reported, except for the peak year, in realization (1948). The generally upward trend of kaolin production in recent years is clearly shown in the accompanying chart (fig. 1).

As in other recent years, kaolin was consumed in 1949 chiefly in four fields—paper manufacture (762,255 short tons or 54 percent of the total china clay), rubber compounding (197,341 tons or 14 percent), pottery (122,328 tons or 9 percent), and refractories (120,816 tons or 9 percent). The remainder was used for a wide variety of purposes, including cement, high-grade tile, fertilizers, insecticides, chemicals, paint filler or extender, calcimine, and linoleum. Decreases in kaolin consumption in 1949 compared with 1948 were reported in the manufacture of high-grade tile (24 percent); whiteware manufacture and refractories (17 percent each); and paper (13 percent). Increases were noted in rubber, glass refractories, foundries, plaster, and unspecified uses.

Kaolin sold or used by producers in the United States, 1948–49, by States

[1] Included with "Other States."
[2] Includes States indicated by footnote 1 and Illinois, Utah, and Virginia.

Shipments of kaolin came from 10 States in 1949, the same number as in 1948, but 90 percent of the total in 1949 was mined in two States—Georgia (71 percent) and South Carolina (19 percent). Pennsylvania ranked third, with 4 percent of the total production. Other States in which kaolin was produced were Alabama, California, Florida, Illinois, North Carolina, Utah, and Virginia. Of the States or groups of States shown in the accompanying table, all except Pennsylvania produced less kaolin in 1949 than in 1948.

Georgia kaolin sold or used by producers, 1945–49, by uses

Year	China clay, paper clay, etc.			Refractory uses			Total kaolin		
	Short tons	Value		Short tons	Value		Short tons	Value	
		Total	Average per ton		Total	Average per ton		Total	Average per ton

Quotations on Georgia kaolin, as reported in E&MJ Metal and Mineral Markets, for filler and ceramic grades were given as $8.50 to $9.50 per ton for crushed material and $13 to $17 for pulverized, in paper bags. Quotations on kaolins used for saggars and as coating clays and "specialties" were discontinued by the above-noted journal after the middle of 1949. North Carolina china clays, ceramic grades in bulk, carlots, were quoted at $18 to $20 per ton, depending on type. Through March 1949, Florida kaolins were quoted by the same source at $16.75 per ton in bulk for washed and crushed material; $20.75 for washed and air-floated clays; and $35 for air-floated enamel clay. In April these quotations were raised to $18.75 per ton for washed and crushed kaolin; $24.25 for washed and air-floated; and $38.50 for air-floated enamel clay and did not change during the balance of the year. Crude Pennsylvania kaolin was quoted throughout 1949 at $5 to $7.50 per ton and "purified" kaolin at $21 to $24.

Prices of imported china clay at the beginning of 1949 were quoted in Oil, Paint and Drug Reporter, ex dock (Baltimore, Boston, Norfolk, and Philadelphia), at $16 to $35 per net ton for white lump in bulk, $45 per ton for powdered material in carlots and powdered, ex warehouse, l. c. l., $50 to $55. Beginning at the end of October (and maintained through the rest of the year), these quotations were given as follows: White lump, carlots, ex dock (Philadelphia and Portland, Maine), $19 to $40 per long ton; powdered, ex dock, in bags, $35 to $45 per net ton; and powdered, l. c. l., ex warehouse, $45 to $60. The average value of domestic kaolin sold or used as reported to the Bureau of Mines in 1949 rose to $13.43 compared with $12.59 in 1948 and $12 in 1947.

Imports of kaolin in 1949 dropped 23 percent compared with 1948 and except for the war years 1941 through 1945, were the smallest receipts at United States ports during the last 50 years. Of the 1949 imports, totaling 77,226 short tons, 76,448 tons originated in the United Kingdom. The remainder comprised small tonnages from Canada and Czechoslovakia.

Exports of kaolin or china clay in 1949 rose 14 percent compared with 1948 to 21,839 short tons, of which 88 percent was shipped to Canada. Small tonnages also were sent to Mexico, Central and South America, Europe, Africa (Union of South Africa), Asia (Japan and Indonesia), and Australia.

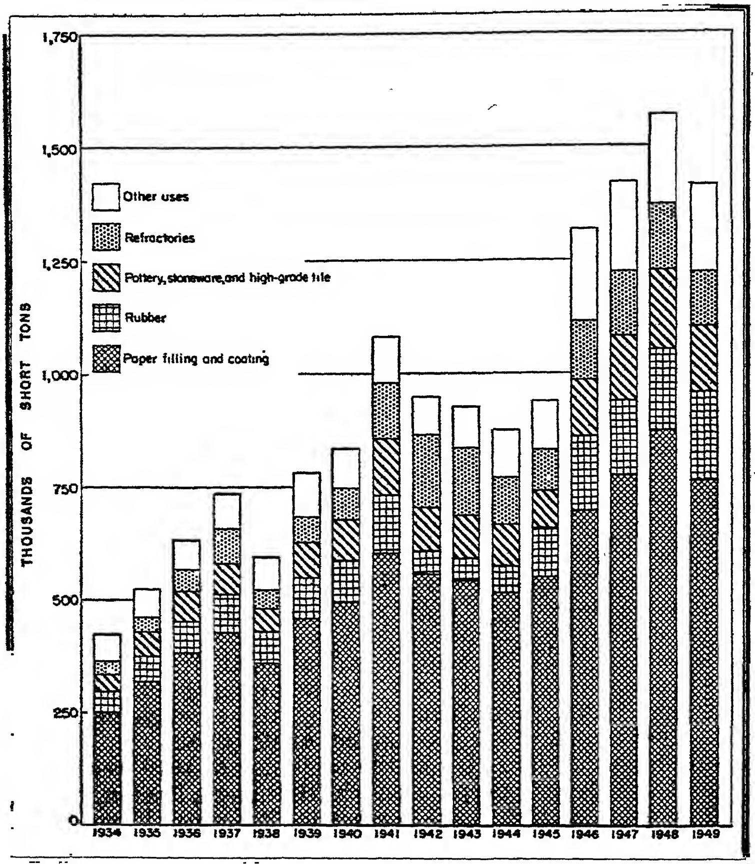

FIGURE 1.—Kaolin sold or used by domestic producers for specified uses, 1934–49.

Prospecting techniques and mining methods in the kaolin-producing States of the Southeast [2] and the dry mining of kaolin in South Carolina [3] were described by Tyler. The preparation and industrial applications of kaolin were described.[4]

BALL CLAY

Sales of ball clay in 1949 were 17 percent less than in 1948 and 8 percent lower in value. The tonnage was slightly higher than the 1945–49 average and larger than in any years except 1947 and 1948. The total value was the second highest recorded, topped only by 1948. For the seventh year, Tennessee has had the largest share of output—53 percent of ball-clay production in 1949, or 132,337 short tons, followed by Kentucky with 36 percent or 89,281 tons. The balance was produced in Maryland, Mississippi, and New Jersey. Kentucky

[4] Kaolin Clays and Their Industrial Uses: J. M. Huber Corp., New York, 1949, 141 pp.

and Tennessee decreased 14 and 24 percent, respectively, compared with 1948; increases were reported from Maryland and New Jersey.

Ball clay sold by producers in the United States, 1947–49, by States

State	1947		1948		1949	
	Short tons	Value	Short tons	Value	Short tons	Value
Kentucky	99,951	$1,072,203	103,426	$1,155,530	89,281	$1,076,531
Maryland, Mississippi, and New Jersey	22,931	262,947	21,756	284,588	27,265	327,427
Tennessee	146,168	1,588,610	173,797	1,902,529	132,337	1,660,481
Total	269,050	2,923,760	298,979	3,342,647	248,883	3,064,439

Ball clays are consumed chiefly in making whiteware; sales for this purpose in 1949 decreased 20 percent compared with 1948. On the other hand, the use of ball clay in high-grade tile, architectural terra cotta, and enameling showed increases (15 percent for high-grade tile and 27 percent for enameling). Over 80 percent (200,142 short tons) of the national output in 1949 was sold for use in pottery; 11 percent (27,349 tons) in high-grade tile; 5 percent (11,603) in refractories; and the remaining 4 percent for enamel, paper filler, and miscellaneous uses.

Price quotations on ball clay in 1949, appearing in E&MJ Metal and Mineral Markets, did not change during the year and were as follows: Tennessee—crude ball clay, $10 per short ton, and air-floated and pulverized, $19.50 per ton; Maryland—shredded, in bulk, $7 to $9, and air-floated, in bags, $14 to $17.50 per ton. No quotations on Kentucky ball clay in 1949 were given in E&MJ Metal and Mineral Markets. The average value per ton of ball clay in 1949 as reported by the producers to the Bureau of Mines was $12.31 compared with $11.18 in 1948 and $10.87 in 1947.

Imports of common blue and ball clay and Gross Almerode clays in 1949 declined 25 percent in quantity and 35 percent in value compared with 1948. Unmanufactured blue and ball clays comprised the major share of the imports; United Kingdom supplied 91 percent of this classification and virtually all the imports of manufactured blue and ball clay. Small tonnages of imports of blue and ball clays came from Canada and Germany. Imports of Gross Almerode clays (from United Kingdom) in 1949 totaled only 459 short tons. Exports, if any, are not separately published.

The mining and processing of ball clay in the United States were described.[5] Advantages of using ball clay and kaolin in dinnerware compositions were noted.[6]

FIRE CLAY

Fire clay sold or used in 1949 decreased 13 percent to 8,571,844 tons from the peak year 1948 (9,849,914 tons). This decline was due in part to the general slackening in industrial demand for refractories and in part to work stoppages in the coal and steel industries.

[5] Bell, Richard, Ball-Clay Mining in the United States: Ceram. Age, vol. 53, No. 4, 1948, pp. [illegible]; Am. Ceram. Soc. Jour., vol. 32, No. 4, Apr. 1, 1949, p. 115 (abs.).

[6] Cox, Paul E., Why Use More Than One Clay in a Body Mixture: Ceram. Age, vol. 53, No. 4, 1948, pp. 202–203; Am. Ceram. Soc. Jour., vol. 32, No. 4, Apr. 1, 1949, p. 109.

Refractories and heavy clay products were the major outlets for fire clay, totaling 4,811,099 and 3,430,723 tons, respectively, a combined total of 96 percent of the total tonnage. About 1 percent each was consumed in the manufacture of high-grade tile and in chemicals and the remainder in a wide variety of uses. Refractories decreased 20 percent in 1949 compared with 1948, but heavy clay products declined only 1 percent. The chief use of fire clay is in making fire brick and block, taking 3,754,420 tons in 1949. Several of the less important uses were larger in 1949 than in 1948—pottery and stoneware, rubber, linoleum, high-alumina brick, clay crucibles, and glass refractories.

In 1949 Ohio ranked first in order of output of fire clay, followed by Pennsylvania, Missouri, Indiana, Kentucky, California, and Illinois. These seven States produced 80 percent of the total. The

[1] Includes stoneware clay as follows: 1948—143,701 tons, $321,062; 1949—103,417 tons, $224,113.
[2] Included with "Other States."
[3] Includes diaspore and burley clay as follows: 1948—diaspore, 52,255 tons, $565,163; burley, 38,393 tons, $295,[illegible]; 1949—diaspore, 25,259 tons, $308,885; burley, 32,432 tons, $204,850.
[4] Includes States indicated by footnote 2 above, and Alaska (1948 only), Delaware, Idaho, Iowa, Kansas, Massachusetts, Michigan (1949 only), Minnesota, Mississippi, Montana, Nebraska, Nevada, New Mexico, North Dakota, Oregon, South Carolina, and Virginia.

remainder was produced in 26 other States. Of the 17 principal producing States shown in the accompanying table, 7 (Arkansas, Colorado, Indiana, Maryland, Tennessee, Utah, and Washington) reported increases and 10 reported decreases.

Price quotations on fire clay do not appear in trade journals. However, average realizations per ton reported to the Bureau of Mines by producers indicated that the average value of fire clay sold in 1949 was $2.91 per ton, compared with $2.90 in 1948. The average value of all fire clay, including both sales and captive tonnage, was $2.96 in 1949 compared with $2.99 in 1948. Quotations on fire-clay products, which during 1948 had been raised three times, remained steady throughout 1949 and were reported by E&MJ Metal and Mineral Markets as follows: Missouri, Kentucky, and Pennsylvania fire-clay brick, first quality, $100 per thousand, and second quality, $80 per thousand; Ohio firebrick, intermediate grade, $74 per thousand, and second-grade, $66 per thousand.

Imports of fire clay are not shown separately in foreign trade statistics. Exports of fire clay in 1949 were 21 percent in tonnage and 18 percent in value less than in 1948, and totaled 80,736 short tons valued at $766,195. Canada took 85 percent of the total exports; Mexico 7 percent; and Chile 2 percent. The remainder (6 percent) comprised small tonnages to 42 destinations in Central and South America, Europe, Asia, and Africa.

Occurrence, chemical analyses, and ceramic tests of the diaspore, burley, flint, and plastic fire clays of Missouri were described [7] and differential thermal analyses published.[8] Utilization and composition of plastic refractories, ramming mixes, and castables were reported.[9]

BENTONITE

After an 11-year period of steadily increasing output, production of bentonite in 1949 decreased 6 percent in tonnage and 3 percent in value compared with 1948. Production and value, however, were the second highest on record. The smaller coal and steel outputs, due to lower general business activity as well as to the work stoppages, directly affected the sale of bentonite to foundries and resulted in a 22-percent drop in sales for use as foundry-sand bond.

As in 1948, bentonite used in the foundry and petroleum industries totaled 92 percent of the total tonnage—rotary-drilling mud accounting for 36 percent (313,083 tons); filtering and decolorizing oils, 35 percent (303,797 tons); and foundry-sand bond, 21 percent (178,867 tons). The remaining tonnage (71,496 tons) was consumed in a wide variety of purposes. Bentonite used for filtering and decolorizing oils rose 5 percent over 1948, and insecticides 19 percent. Nine States reported outputs of bentonite in 1949. Increases in tonnage were noted for Arizona and Utah and decreases for California, Mississippi, Montana, South Dakota, and Wyoming. Production was reported in Idaho for the first time. Trends in sales for principal uses are shown in an accompanying chart (fig. 2).

Other States [2]	294,399	1,093,985	332,442	1,367,658	351,625	1,563,961
Total	763,889	5,949,586	921,560	7,136,308	867,243	6,938,752

[1] Included with "Other States."
[2] Arizona, California (1949 only), Colorado (1948 only), Idaho (1949 only), Mississippi, Montana, Nevada (1948 only), and Utah.

The Wyoming-South Dakota area supplied 56 percent of the total bentonite in 1949 (Wyoming, 40 percent, and South Dakota, 16 percent) compared with 59 percent in 1948. Texas furnished 3 percent of total sales, the same as in 1948, and the remainder was produced in Arizona, California, Idaho, Mississippi, and Montana.

Wyoming bentonite in 1949 was quoted in E&MJ Metal and Mineral Markets at the same figures as in 1948—dried, crushed, in bulk, $8 per ton; and 200-mesh, pulverized, in 100-pound bags, $11. The average realization per ton as compiled from reports of producers to

the Bureau of Mines rose to $8 per ton in 1949 compared with $7.74 in 1948 and $7.79 in 1947.

Imports of bentonite in 1949 were very small and originated in Africa. Exports of bentonite are not shown separately in foreign trade statistics and are included under the blanket classification of "other clays or earth, not specifically provided for." It is understood, however, that some domestic producers export part of their production to widely distributed destinations throughout the world.

Numerous articles on bentonite were published during 1949. A description of open-pit strip mining methods in the recovery of bentonite in Arizona was published.[10] An account of the origin, occurrence, and current mining and processing practices of bentonite in the Black Hills region of South Dakota was presented.[11] The Wyo-Dak Chemical Co., Upton, Wyo., was reported to be building a new milling plant.[12] Detailed tests of white-firing bentonite in Fayette, Gonzales, and Karnes Counties, Tex., revealed commercial quantities of good-quality material.[13] Suggested uses also were given. Fluorescence of Wyoming bentonites was studied.[14]

A refractory lining made of ganister, silica flour, and bentonite was patented.[15] Use of bentonite in preparing pottery bodies to promote plasticity was said to improve the body mix.[16] The relationship of particle size of montmorillonite to its base-exchange capacity was studied and comparisons with kaolinite were presented.[17] Experiments at various temperatures indicated the efficiency of montmorillonite as a cracking catalyst.[18] The use of small quantities of bentonite mixed with hard wheat flour increased both volume and weight of the loaf.[19]

The bentonite industry in Manitoba;[20] the occurrence, mineralogy, and physical properties of Argentine bentonites;[21] and deposits and utilization of Australia's swelling and nonswelling bentonites[22] were described.

FULLER'S EARTH

The production of fuller's earth in 1949 declined 6 percent in quantity and 1 percent in value compared with 1948. The output (320,906 tons) was greater than the average for the 5-year period 1945–49 (317,435 tons) and was the fourth-largest year on record. Distri-

bution of production by major uses for 1940 to 1949 contrasted with the distribution pattern in 1930 is shown in the accompanying chart (fig. 3). Newer uses, such as insecticides and absorbents, have been responsible for the higher outputs in recent years.

Fuller's earth consumed in mineral-oil refining in 1949 totaled 151,353 tons, or 47 percent of the total output, compared with 57 percent in 1948. Absorbent uses accounted for 69,070 tons (22 percent of the total, the same ratio as in 1948); insecticides, 37,342 tons (12 percent of the total in 1949, compared with 5 percent in 1948); rotary-drilling mud, 30,411 tons (9 percent compared with 7 percent in 1948); and vegetable-oil refining, 19,806 tons (6 percent in 1949 compared with 7 percent in 1948). The remainder was used in other filtering and clarifying, binders, and other unspecified uses. Increases in tonnage in 1949 over 1948 were registered only by rotary-drilling mud and insecticides.

States increasing output over 1948 were California, Mississippi, Tennessee, and Texas; the others reported decreases. Florida and Georgia combined accounted for 57 percent of the total tonnage and Texas 31 percent.

Fuller's earth sold or used by producers in the United States, 1947–49, by States

State	1947		1948		1949	
	Short tons	Value	Short tons	Value	Short tons	Value
Florida and Georgia	168,557	$2,699,660	188,014	$3,224,169	181,993	$3,194,551
Illinois	37,740	388,955	37,942	410,678	9,104	118,647
Texas	102,901	1,199,726	92,310	1,162,336	100,745	1,242,558
Other States [1]	19,870	372,273	23,815	476,668	29,064	643,886
Total	329,068	4,660,614	342,081	5,273,851	320,906	5,199,642

[1] Includes California, Mississippi, Nevada, Tennessee, and Utah.

As reported in E&MJ Metal and Mineral Markets, no change occurred in quotations on Georgia and Florida fuller's earth in 1949 compared with 1948, and prices were quoted as follows: 30- to 60-mesh, $14.50 per short ton; 14- to 30-mesh, $14; 200-mesh up, $10; and 100-mesh up, $7. Average value of fuller's earth sold or used as reported to the Bureau of Mines by producers was $16.20 in 1949, compared with $15.42 in 1948 and $14.16 in 1947.

Imports of fuller's earth in 1949 totaled only 389 short tons, largely from United Kingdom, with small amounts from Canada and Australia. Exports are not given separately in official foreign statistics. Reports from the producers to the Bureau of Mines, however, indicated exports of approximately 12,100 short tons in 1949, compared with 10,600 tons in 1948. Destinations reported included Canada, Central and South America, Netherlands West Indies, several European nations, Bahrein Island, Saudi Arabia, and the Philippines.

A new percolation type of fuller's earth was introduced.[23] A process for revivifying spent absorbent earths by burning out carbonaceous impurities, using a multistage process, was patented.[24] Comparisons

of natural and treated absorbent earths from the United States and five other countries were given in a recent French publication.[25]

MISCELLANEOUS CLAYS

This section includes statistics for clays and shales (large tonnages of which are used in the manufacture of heavy clay products and portland cement) other than those discussed in the preceding pages. With these clays are grouped small tonnages of slip clay, oil-well drilling mud, pottery clay, and other clays that cannot be clearly identified with one of the types given separate treatment in this chapter.

Production of miscellaneous clays in 1949 continued at a high level, with a 4-percent drop in tonnage compared with 1948. In 1949, 69 percent of the total miscellaneous clays was used in the manufacture of heavy clay products and 28 percent in cement. Tonnage consumed in heavy clay products was 7 percent less than in 1948 and quantities used in cement manufacture rose 4 percent.

For the past 3 years (1947–49), 96 percent of the clay and shale for which figures are given in this section was captive tonnage—mined by the clay-products companies near their processing plant and first marketed as brick, cement, tile, or other finished products. The average value of the miscellaneous clay sold as raw or prepared clay in 1949 was $1.66 compared with $1.89 in 1948 and $1.99 in 1947. Some of the special types of clay included under the "miscellaneous" clay classification, however, sold for much higher values. The value of the captive tonnage was computed from individual estimates that generally are $1 or less per ton.

Miscellaneous clays, which include the so-called common or surface clays and shales, are widely distributed and producing deposits

[1] Includes slip clay as follows: 1948—Michigan and New York; 1949—Indiana, Michigan, and New York; figures cannot be shown separately. Purchases by portland cement companies of common clay and shale: 1948—472,556 tons, estimated at $362,853; 1949—559,682 tons, estimated at $494,147.
[2] Includes the following: Common clay and shale used by portland cement companies: 1948—5,888,962 tons, estimated at $3,761,284; 1949—6,058,502 tons, estimated at $3,866,210.
[3] Included under "Undistributed."
[4] Figures include Alaska, Arizona, Delaware, District of Columbia, Florida, Idaho, Mississippi, North Dakota, Puerto Rico, South Dakota, Vermont, Virginia, and States indicated by footnote 3.
[5] Figures include Arizona, Delaware, District of Columbia, Florida, Idaho, Nevada, North Dakota, South Dakota, Vermont, Virginia, and States indicated by footnote 3.

occur in all States (except Rhode Island). States reporting a production of over 1 million tons in 1949, in order of output, were: Ohio, California, Illinois, Pennsylvania, Texas, Michigan, New York, North Carolina, and Alabama. Of the States for which data are shown in the accompanying table, 19 reported increases in output, and 18 reported decreases in 1949 compared with 1948.

HEAVY CLAY PRODUCTS

The total value of shipments of the principal structural clay products in 1949 declined to $262,000,000 compared with $268,000,000 in 1948—a decrease of 2 percent, according to the Bureau of the Census. Shipments of all classes of products shown except hollow facing tile and unglazed structural tile were smaller in 1949 than in 1948. Shipments of unglazed brick and floor and wall tile declined 8 and 9 percent, respectively, compared with 1948, and vitrified-clay sewer-pipe and drain-tile shipments each decreased 6 percent. Unglazed structural

Shipments of principal structural clay products in the United States, 1947–49 [1]

Production and shipments of refractories in the United States, by kind, 1948–49

[Bureau of the Census]

Product	Unit of quantity	1948			1949		
		Production (quantity)	Shipments		Production (quantity)	Shipments	
			Quantity	Value (in thousands of dollars)		Quantity	Value (in thousands of dollars)
Clay refractories:							
Fire-clay brick, standard and special shapes, except superduty.	1,000 9-in. equiv.	655,471	649,745	58,948	523,623	514,378	48,819
Superduty fire-clay brick, standard and special shapes.	do	66,515	62,025	8,321	57,353	51,586	7,680
High-alumina brick, standard and special shapes (50 percent Al_2O_3 and over, except fused alumina and mullite).	do	22,498	20,708	4,896	16,459	16,346	4,392
Insulating firebrick, standard and special shapes.	do	43,668	36,804	5,997	29,239	33,315	5,840
Ladle brick	do	185,497	184,052	9,526	164,089	159,790	8,557
Hot-top refractories	do	52,345	53,284	4,760	34,560	34,284	3,261
Sleeves, nozzles, runner brick and tuyères.	do	51,659	51,845	5,662	40,310	39,189	4,802
Glass-house pots, tank blocks, upper structure, and floaters.	Short tons	25,305	25,505	3,404	17,218	17,564	2,539
High-temperature bonding mortars.	do	68,825	68,254	4,675	54,462	53,829	4,146
Plastic refractories (including wet and dry ramming mixtures).	do	110,345	109,063	4,250	79,386	77,080	3,701
Cast and castables (hydraulic setting).	do	52,852	51,754	3,272	47,437	47,675	3,430
Ground crude fire-clay and high-alumina material.	do	350,378	350,432	3,191	329,470	327,864	2,943
Other clay refractories				2,457			2,034
Total clay refractories				119,359			102,144
Nonclay refractories:							
Silica brick, standard and special shapes.	1,000 9-in. equiv.	321,443	318,203	34,118	266,596	261,719	30,320
Magnesite and magnesite-chrome (magnesite predominating) brick, standard and special shapes.	do	24,462	24,556	11,717	18,508	18,650	9,279
Chrome and chrome-magnesite (chrome predominating) brick, standard and special shapes.	do	41,706	41,077	16,073	35,847	34,777	14,312
Graphite and other carbon crucibles and retorts.	Short tons	11,535	11,431	5,384	7,180	7,328	3,628
Other graphite and carbon refractories.	do	1,217	1,157	445	846	814	298
Silicon carbide				14,704			6,116
Mullite and kyanite							2,454
Sillimanite							356
Fused alumina and bauxite							2,530
Zirconia, forsterite, fused magnesia, pyrophyllite, and other nonclay shapes.							1,693
High temperature bonding mortars.	Short tons	36,851	36,907	3,697	30,954	30,820	3,332
Plastic refractories (including wet and dry ramming mixtures).	do	88,539	88,328	5,630	72,339	72,015	4,934
Other nonclay refractory materials, sold in lump or ground form (including ground silica and nonclay cast and castables).				2,616			2,875
Total nonclay refractories [1]				94,384			82,027
Grand total refractories [1]				213,743			184,171

[1] Data for dead-burned magnesia or magnesite excluded to avoid duplication in other refractory products covered in this table (such as magnesite brick and shapes). Quantity and value of shipments of dead-burned magnesia or magnesite totaled 305,000 tons valued at $11,421,000 in 1948, and 218,000 tons valued at $8,606,000 in 1949.

tile, however, was slightly above 1948, while hollow facing tile in 1949 rose 11 percent above 1948.

After the reconversion period following World War II, production and shipments of refractories were stimulated by the general business expansion and the augmented industrial production required to satisfy pent-up civilian and industrial needs. The increased refractory output continued through 1948 and the early part of 1949. The coal and steel stoppages then resulted in curtailed production and were the chief factors in a 14-percent drop in value of shipments of clay refractories in 1949 as against the 1948 total. The value of shipments of fire bricks (except superduty) was $48,819,000, 17 percent under 1948; of superduty fire-clay brick, 8 percent under 1948; and of ladle brick, 10 percent under 1948.

TECHNOLOGY

The year was marked by active research into the use of clays in structural products, including lightweight aggregate. This emphasis on long-term research resulted in formation of the Structural Clay Products Research Foundation to foster and carry forward the $1,250,000 5-year investigation into all phases of the brick and tile industry.[26] A new research agency, the Brick and Tile Research Institute, was organized to advance the interests of the brick and tile manufacture in the Southeast.[27]

The use of common clays in making lightweight aggregates, utilizing their bloating characteristics, is increasing, and methods and developments were described.[28]

A brief yet comprehensive survey of the whole field of lightweight aggregates was published.[29] The addition of soda ash in controlled amounts is claimed to improve the working properties of a clay mix.[30] The nonceramic uses of clays were discussed briefly.[31] An investigation of the fire-resistant qualities of structural clay partitions [32] was undertaken. A detailed discussion of laboratory procedure and methods of analysis of clays was published.[33] A new foundry molding sand treatment method was reported.[34]

Publications were issued describing clay resources of southern Arkansas,[35] New York,[36] Ohio,[37] Lawrence County, Ind.,[38] Pennsylvania,[39] and Fergus County, Mont.[40]

An extensive compilation of occurrences in the United States of kaolin, montmorillonite, bentonite, illite, attapulgite, and pyrophyllite [41] and a glossary of clay mineral names also were published.[42]

A number of articles appeared on fuels in the ceramic industries.[43]

The International Geological Congress meeting in London in 1948 sponsored the formation of an International Committee to correlate studies of clays, facilitate contact between specialists in this field, and interchange information.[44]

A discussion of firing tests on Philippine refractory clays and their utilization was published.[45] Papers on clays and shales in France,[46] Austria,[47] and western Siberia,[48] Saskatchewan,[49] Australia,[50] United Kingdom,[51] and India [52] were issued. The use of an extremely finely ground Canadian clay from British Columbia in pharmaceutical and cosmetic preparations was reported.[53] Thermal analyses of certain Japanese clays were made.[54]

Coal—Bituminous and Lignite [1]

By W. H. Young, R. L. Anderson, and E. M. Hall

SURVEY OF THE BITUMINOUS-COAL AND LIGNITE INDUSTRY IN 1949

THE production of soft coal in 1949—an estimated output of 435,000,000 tons [2]—decreased 27 percent from the 599,518,229 tons produced in 1948. Decreased production was due to work stoppages, reduced exports, and diminished domestic demand. According to the Bureau of Labor Statistics, there were 421 strikes in soft-coal mines in 1949, with 1,130,000 workers involved and 16,700,000 man-days lost (an average of 15 days per man on strike).

Production.—Production was high during the first 6 months of 1949, generally exceeding 11,000,000 tons per week, except during strikes. During the last 6 months output averaged close to the 7,000,000-tons-per-week level.

Consumption.—All classes of consumers, except retail-dealer deliveries, used less coal in 1949 than in 1948. There was only a slight increase for retail-dealer deliveries. The total consumption in 1949 was approximately 74,000,000 tons less than in 1948. Table 5 shows trends in consumption for the major classes of consumers.

Changes in Stocks.—The reserve supply of bituminous coal and lignite in the hands of industrial consumers and retail coalyards decreased from 69,373,000 tons at the beginning of 1949 to 45,111,000 tons at the close. The days' supply of stocks decreased from 46 to 32. Stocks on the upper Lake docks decreased 4,026,981 tons from January 1 to December 31, 1949.

Mechanization.—The quantity of coal loaded mechanically at underground mines in the United States was less in 1949 than in 1948. However, the percentage mechanically loaded increased from 64 percent of the total underground output in 1948 to 67 percent in 1949. Sales of underground loading equipment, in terms of capacity, were less in 1949 than in any year since 1935.

Mechanical Cleaning.—The total capacity of mechanical-cleaning equipment sold for use at bituminous-coal mines in 1949 was estimated at 13,300 tons of cleaned coal per hour, a decrease of 25 percent from the previous year.

[1] Data for 1949 are preliminary; final figures will be issued in a Mineral Market Report about November 1950. Data for 1948 are final.

[2] Throughout this chapter, "tons" refers to net tons of 2,000 pounds, except that the world table is in metric tons of about 2,205 pounds.

Trend of Employment.—The average number of men working daily at bituminous-coal and lignite mines in 1949 decreased to 375,000 from 441,631 in 1948.

Index to Capacity.—As it is not possible for all mines to operate every working day in the year, a conservative figure of 280 days for calculating potential capacity was suggested some years ago by the coal committee of the American Institute of Mining and Metallurgical Engineers. (See Minerals Yearbook, 1935, pp. 631–632.) The average output per day worked in 1949 was 2,416,667 tons, which (if applied to 280 days) gives an annual potential output of 677,000,000 tons, compared with the actual production of 435,000,000 tons.

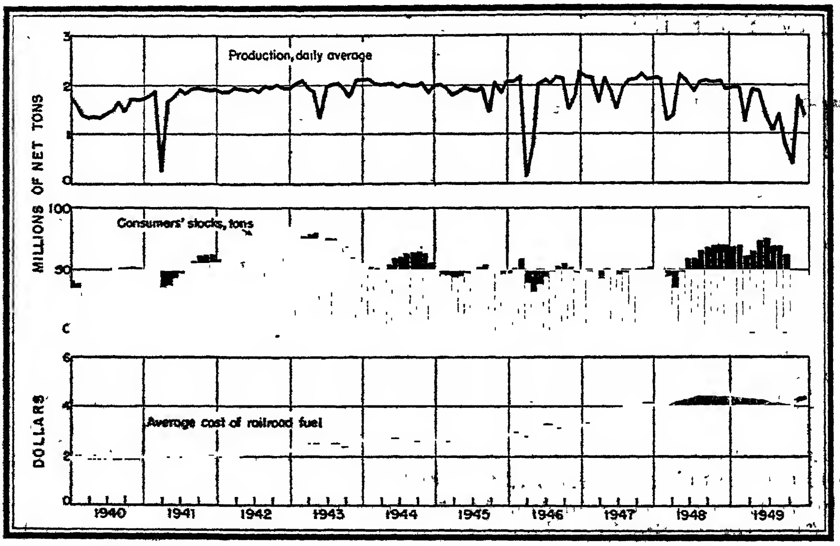

FIGURE 1.—Trends of production, stocks, and prices of bituminous coal and lignite in the United States, 1940–49.

Trends of Fuel Efficiency.—Since 1942 there has been no definite trend in fuel efficiency for the various consuming industries. During 1949 electric public-utility power plants attained increased fuel efficiency.

Competition With Oil and Gas.—Soon after the war, increased competition among the fuels developed, with numerous reports of conversion from coal to fuel oil and gas.

Electric-power utilities consumed 16 percent less bituminous coal, 56 percent more fuel oil, and 15 percent more gas in 1949 than in 1948.

Class I railroads decreased their consumption of coal 28 percent in 1949 and their purchases of fuel oil and Diesel oil 16 percent from 1948 purchases.

The manufacture of domestic coal-burning equipment is reflected in statistics published by the Bureau of the Census. Factory sales of domestic stokers for burning bituminous coal decreased from 61,359 in 1948 to 21,527 in 1949. Shipments of domestic oil burners, boiler-burner units, and furnace-burner units increased from 392,625 (revised figure) in 1948 to 567,515 in 1949.

FIGURE 2.—Production of bituminous coal and lignite in the United States, by weeks, 1948–49.

SOURCES OF DATA

Bituminous-coal- and lignite-production statistics for 1949 are preliminary estimates based upon (1) weekly or monthly reports of railroad carloadings of coal and beehive coke by all the important carriers, (2) shipments by river as reported by the United States Army Engineers, (3) direct reports from a number of mining companies, and (4) monthly production statements compiled by certain local operators' associations and State mine departments. In the estimates for 1949, allowance has been made for commercial truck shipments, local sales and colliery fuel, and small trucking or wagon mines producing 1,000 tons a year or more.

Data for 1948 are final and based upon detailed annual reports of production and mine operation furnished by the producers. As in previous years, all but a small percentage of the output was covered by the reports submitted. For the remaining output not directly reported—consisting chiefly of small mines—it has been possible to obtain reasonably accurate data from the records of the State mine departments, which have statutory authority to require such reports, or, in a few instances, from railroad carloadings.

In accordance with the practice followed by the Bureau of Mines in previous years, the statistics in this report relate to mines having an output of 1,000 tons a year or more and do not attempt to include many small mines producing less than 1,000 tons a year.

These data include all coal except Pennsylvania anthracite.

SALIENT STATISTICS

TABLE 1.—Salient statistics of the bituminous-coal and lignite industry in the United States, 1948–49

[All tonnage figures represent net tons]

	1948	1949 (preliminary)	Change in 1949
			Percent
Production	599,518,229	435,000,000	−27.4
Consumption	519,909,000	445,732,000	−14.3
Stocks at end of year:			
Industrial consumers and retail yards	69,373,000	45,111,000	−35.0
Stocks on upper Lake docks	7,288,977	3,261,996	−55.2
Imports and exports: [1]			
Imports	291,337	314,980	+8.1
Exports	45,930,133	27,842,056	−39.4
Price indicators (average per net ton):			*Dollars*
Average cost of railroad fuel purchased, f. o. b. mines [2]	$4.34	$4.36	+0.02
Average cost of coking coal at merchant coke ovens [3]	$8.74	$9.00	+.26
Average retail price [4]	$15.40	$15.83	+.43
Average railroad freight charge per net ton [5]	$2.74	$2.95	+.21
Average value of production, f. o. b. mines [6]	$4.99	$4.85	−.14
Underground loading machinery sold: [7]			*Percent*
Mobile loading machines (number)	723	286	−60.4
Scrapers (number)	17	8	−52.9
Conveyors, including those equipped with duckbills (units)	1,025	394	−61.6
"Mother" conveyors (units)	230	116	−49.6
Surface stripping	139,505,920	99,000,000	−29.0
Mechanically loaded underground	295,806,285	226,000,000	−23.6
Mechanically cleaned	180,883,323	137,000,000	−24.3
Number of mines [8]	9,079	9,000	−.9
Average number of days worked [8]	217	180	−17.1
Average number of men working daily [8]	441,631	375,000	−15.1
Production per man per day [8]	6.26	6.44	+2.9
Fuel efficiency indicator:			
Pounds of coal per kilowatt-hour at electric power plants [9]	1.30	1.25	−3.8

[1] U. S. Department of Commerce. Exports for 1948 are revised.
[2] Interstate Commerce Commission (class I steam railways, including class I switching and terminal companies). Excludes freight charges.
[3] As reported by coke operators.
[4] Bureau of Labor Statistics, U. S. Department of Labor.
[5] Average receipts per net ton of revenue bituminous coal and lignite originated, as reported by the Interstate Commerce Commission.
[6] Average gross realization, selling cost not deducted.
[7] Young, W. H., and Anderson, R. L., Sales of Mechanical Loading and Cleaning Equipment: Coal Age, February 1950, pp. 81–83; Min. Cong. Jour., February 1950, pp. 100–103; Mechanization, February 1950, pp. 56–58.
[8] Based upon reports of mine operators producing 1,000 tons and over. The number of men working represents man-days of labor divided by days the tipples operated.
[9] Federal Power Commission.

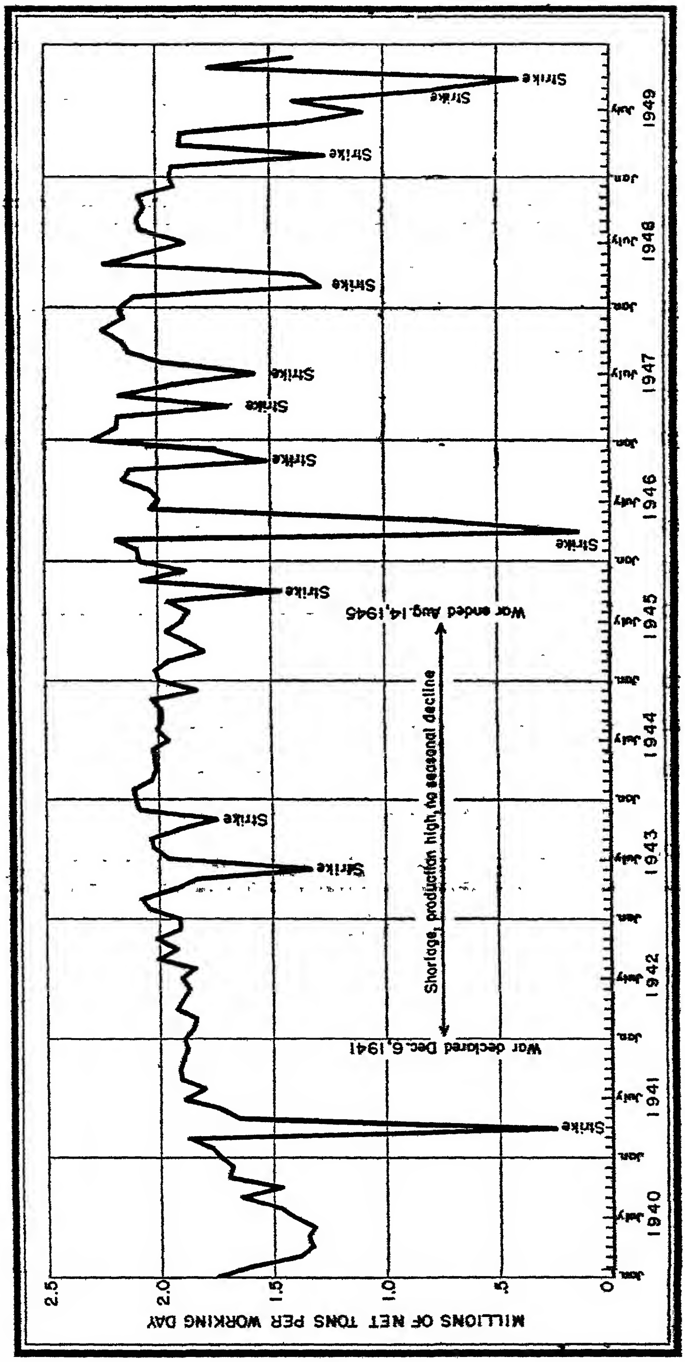

FIGURE 3.—Average production of bituminous coal and lignite in the United States per working day in each month, 1940–49.

PRODUCTION BY WEEKS AND MONTHS

The following tables summarize the preliminary statistics of weekly and monthly production of bituminous coal and lignite in 1949. The estimates given are based upon the latest information available and differ in some instances from the current figures published in the Weekly Coal Reports.

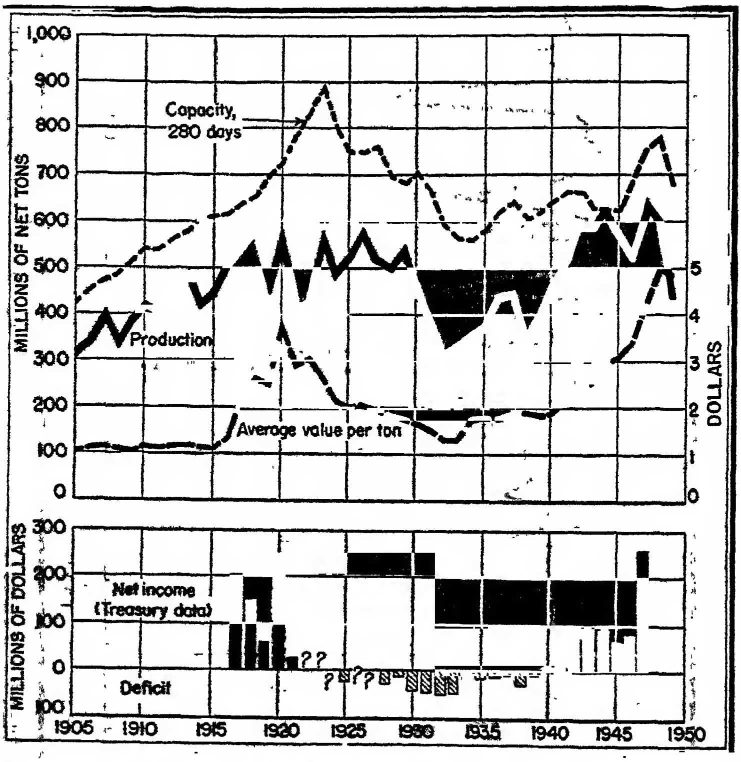

FIGURE 4.—Trends of bituminous-coal and lignite production, realization, mine capacity, and net income or deficit in the United States, 1905–49.

TABLE 2.—Estimated weekly production of bituminous coal and lignite in the United States in 1949

[1] Federal Power Commission. Represents latest available revised figures for bituminous coal and lignite consumed by public-utility power plants in power generation, including a small quantity of coke amounting to approximately 100,000 tons annually.

[2] Bureau of Census, U. S. Department of Commerce.

[3] Association of American Railroads. Represents consumption of bituminous coal and lignite by class I railways for all uses, including locomotive, powerhouse, shop, and station fuel. The Interstate Commerce Commission reports that in 1948 consumption for all uses by class I line-haul railways, plus purchases for class II and class III railways, plus purchases by all switching terminal companies combined was 99,793,401 tons of bituminous coal and lignite.

[4] Includes a small amount of anthracite.

[5] Estimates based upon receipts collected from a selected list of representative manufacturing plants and retail dealers.

[6] The total of classes shown approximates grand total consumption. It is not appropriate to "calculate" consumption from production, imports, exports and changes in stocks because certain significant items of stocks are not included in year-end stocks. These items are: Stocks on Lake and Tidewater docks, stocks at other intermediate storage piles between mine and consumer, and coal in transit.

[7] Preliminary figures.

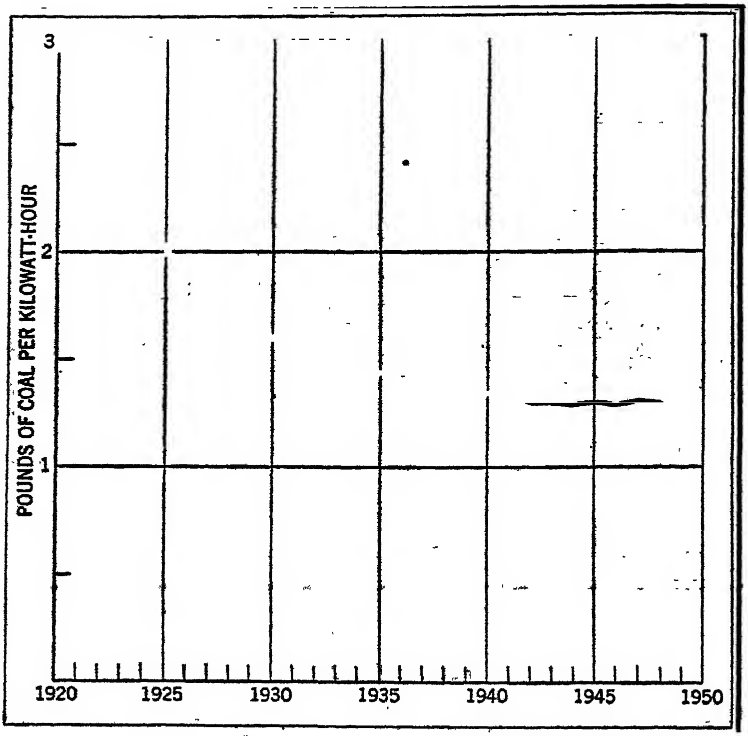

FIGURE 6.—Trend in fuel economy at electric-utility power plants in the United States, 1920–49.

RELATIVE RATE OF GROWTH OF COAL, OIL, AND WATER POWER, 1889–1949

The total supply of available energy in the form of coal, oil, natural gas, and water power in 1949 was 31,786 trillion B. t. u.—a 13.2 percent decrease from 1948.

The figures are expressed in British thermal units because some common denominator is necessary for such unlike quantities as tons of coal, barrels of oil, and cubic feet of gas. Table 7 summarizes the equivalent of each of the fuels in trillions of British thermal units. Water power is represented by the equivalent fuel required to perform the same work. The table covers the years 1889 and 1899 to 1949.

In converting water power to its equivalent of fuel required to perform the same work, the *prevailing* or average performance of all fuel-burning central electric stations for each year in question has been used. This average has declined from about 7.05 pounds of coal per kilowatt-hour in 1899 to 1.25 in 1949, which shows the influence of improving fuel efficiency. The *prevailing* fuel equivalent closely approximates the quantity of fuel that would have been needed in any one year to generate the same power in a steam-electric station. It should be noted, however, that the ultimate use of the water power generated often displaces fuel burned much less efficiently than in central stations and that no other important branch of fuel consump-

tion has made advances in fuel efficiency approaching that of the central stations. As these tables attempt to determine the total energy from all fuels and from water power, the ideal factor for converting water power into fuel equivalent would be the average efficiency of all forms of fuel consumption in each year. No basis for determining such an all-embracing average exists at present, but enough is known to make certain that it would show much less reduction from 1899 to 1949 than do the central stations.

The figures for oil represent production of crude petroleum and imports; the figures for natural gas represent marketed production. Most of this production does not come into direct competition with coal. Much of the supply of both oil and gas is used in regions of the country, such as California and portions of the Southwest, where coal

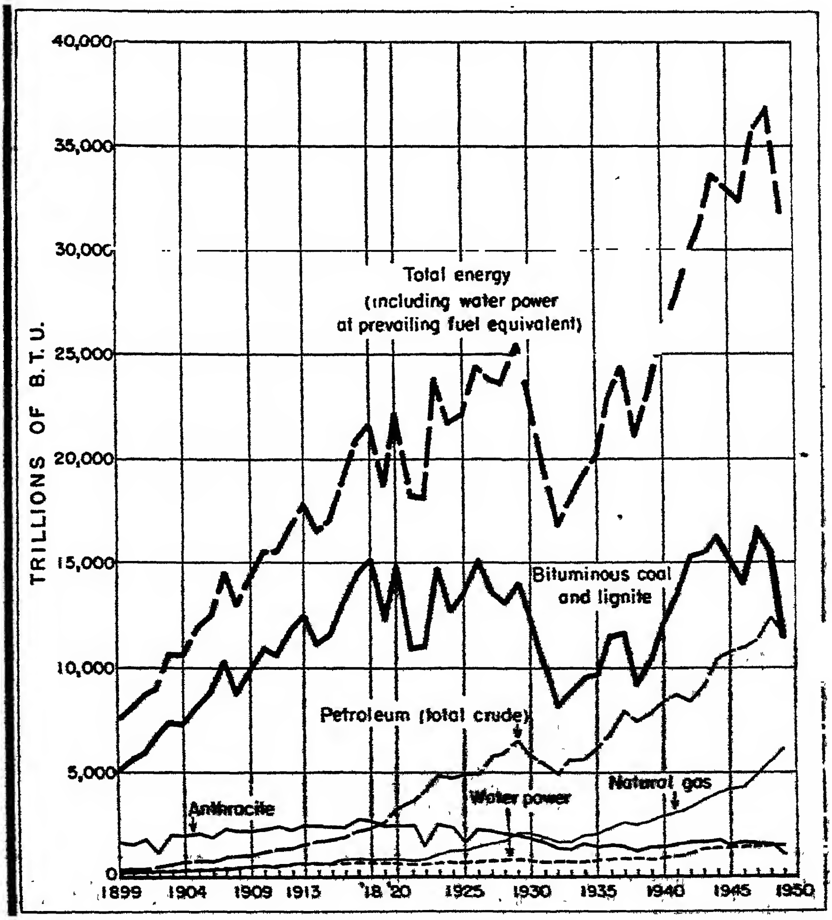

FIGURE 7.—Annual supply of energy from mineral fuels and water power in the United States, 1899–1949.

is available only at unusually high cost because of heavy transportation charges. Nearly half of the natural gas is used in the field for drilling or operating oil and gas wells and pipelines or for the manufacture of carbon black. More than half of the oil is used in the form of gasoline, kerosine, and lubricants, for which purposes coal cannot well compete, except at very much higher levels of oil prices. Even these refined products, however, involve a certain measure of indirect competition with coal, for the energy market of the country is becoming more fluid and competitive, and a demand that cannot be met by one source of supply tends to fall back on the others.

The subject of interfuel competition is exceedingly complex, and an elaborate analysis and the accumulation of data not now available would be required to determine even approximately how much of any one fuel actually has been displaced either by other fuels or by water power. The present tables do not permit determination of such displacement; their purpose is rather to measure the long-time trends in the total demand for energy.

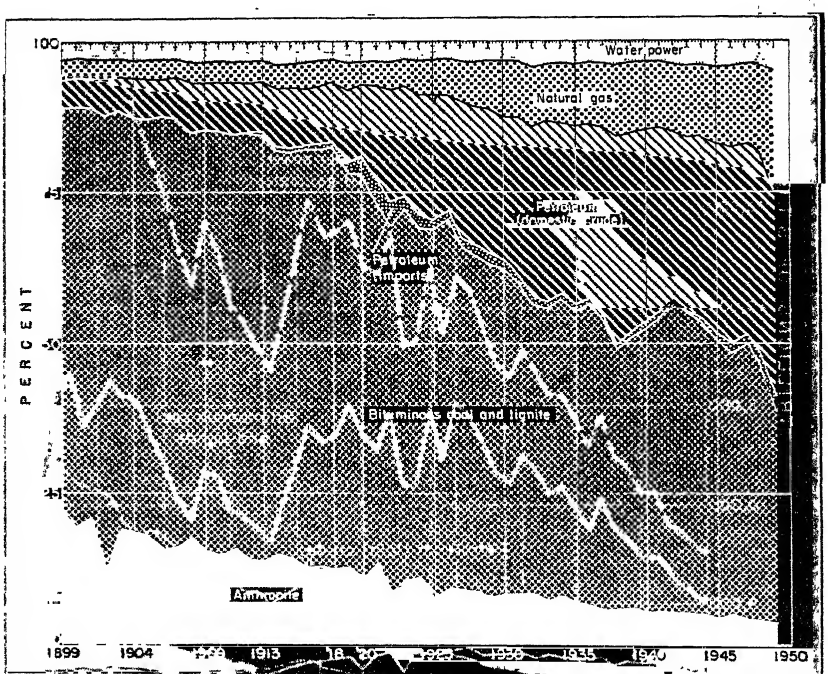

FIGURE 8.—Percentage of total British thermal units equivalent contributed by the several sources of energy in the United States, counting water power at the prevailing fuel equivalent of central stations in each year, 1899–1949.

TABLE 7.—Annual supply of energy from mineral fuels and water power in the United States, 1889 and 1899–1949, in trillions of British thermal units[1]

[1] The unit heat values employed are: Anthracite, 12,700 B. t. u. per pound; bituminous coal and lignite, 13,100 B. t. u. per pound; petroleum 5,800,000 B. t. u. per barrel; natural gas, 1,075 B. t. u. per cubic foot. ~~Water power includes installations owned by manufacturing plants and mines as well as Government and~~ privately owned public utilities. The fuel equivalent of water power is calculated from the kilowatt-hours of power produced wherever available, as it is of all public-utility plants since 1919. Otherwise, the fuel equivalent is calculated from the reported horsepower of installed water wheels, assuming a capacity factor of 20 percent for manufacturers and mines and of 40 percent for public utilities.

[2] Fuel equivalent calculated by assuming the average central-station practice for each of the years for which data are available.

[3] Data not available.

[4] Preliminary figures.

FINAL BITUMINOUS-COAL AND LIGNITE STATISTICS FOR 1948

Tables 11 to 52 give final detailed statistics of bituminous-coal and lignite mine operations in 1948. The subjects covered include production, number and size of mines, employment, value, mechanization, exports, and world production.

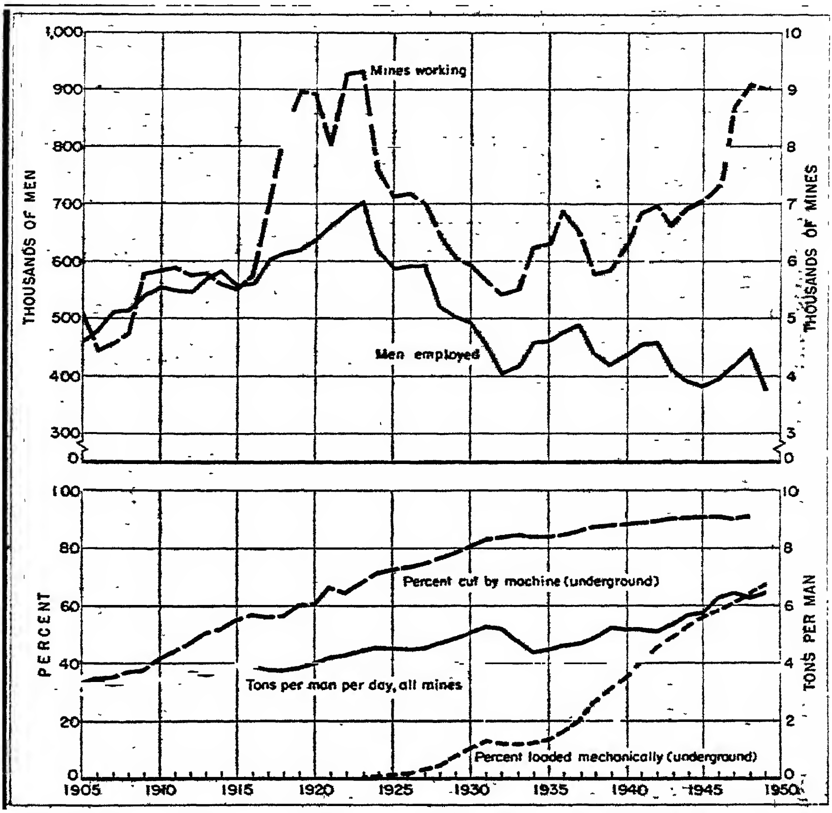

FIGURE 9.—Trends of employment, mechanization, and output per man at bituminous-coal and lignite mines in the United States, 1905–49.

SALIENT TRENDS

TABLE 11.—Salient trends in bituminous-coal and lignite mining industry in the United States, 1941–48

	1941	1942	1943	1944	1945	1946	1947	1948
Production:								
Loaded at mine for shipment by rail [1] net tons	425,184,319	482,814,042	495,863,581	527,135,489	490,471,988	450,615,524	527,281,632	498,193,877
Loaded at mine for shipment by water [2] do	30,240,489	34,018,025	30,188,093	31,518,334	27,547,679	24,641,533	29,802,779	26,734,786
Shipped by truck or wagon do	40,058,638	45,154,432	42,432,667	40,123,023	41,477,428	42,730,884	55,859,262	58,260,437
Taken by locomotive tenders at tipple do	1,099,582	920,213	779,154	807,679	694,555	731,748		
Shipped by conveyor or tram to point of consumption do	6,067,697	7,121,116	7,476,717	7,206,392	6,416,327	5,700,870		
Used by mine employees do	1,872,026	2,180,077	2,549,775	2,545,343	2,660,039	2,464,300	17,080,049	16,329,129
Used at mines for power and heat do	2,483,950	2,708,312	2,701,828	2,713,073	2,442,398	1,950,645		
Made into beehive coke at mines do	7,140,544	7,776,720	8,185,254	7,526,907	5,906,913	5,086,564		
Total production do	514,149,246	582,692,937	590,177,069	619,576,240	577,617,327	533,922,068	630,623,722	599,518,229
Number of active mines of commercial size:								
Class 1 (200,000 tons or more) number	730	811	855	828	753	706	801	755
Class 2 (100,000 to 200,000 tons) do	437	484	464	559	591	560	618	580
Class 3 (50,000 to 100,000 tons) do	402	445	481	540	629	637	704	768
Class 4 (10,000 to 50,000 tons) do	1,305	1,492	1,544	1,776	1,920	2,016	2,665	2,697
Class 5 (1,000 to 10,000 tons) do	3,948	3,740	3,276	3,225	3,140	3,414	3,912	4,279
Total number 1,000 tons and over do	6,823	6,972	6,620	6,928	7,033	7,333	8,700	9,079
Average number of men employed at mines active:								
Underground men	376,765	374,654	326,763	301,461	290,001	[3] 296,030	[3] 311,369	[3] 330,292
Surface:								
In strip pits do	10,861	12,893	16,643	21,035	23,261	[3] 25,408	[3] 29,783	[3] 32,178
All others do	69,355	74,444	72,601	70,851	69,838	[3] 74,996	[3] 78,030	[3] 79,161
Total do	456,981	461,991	416,007	393,347	383,100	[3] 396,434	[3] 419,182	[3] 441,631
Average number of days mines operated	216	246	264	278	261	214	234	217
Capacity of active mines with existing labor force, per year of 280 days net tons	666,000,000	663,000,000	626,000,000	624,000,000	620,000,000	699,000,000	755,000,000	774,000,000
Output per man per day do	5.20	5.12	5.38	5.67	5.78	6.30	6.42	6.26
Output per man per year do	1,125	1,261	1,419	1,575	1,508	1,347	1,504	1,358
Undergound output cut by machine do	408,510,296	462,344,719	461,051,743	469,458,349	424,726,432	382,133,540	442,191,535	460,012,309
Percent of underground output cut by machine	89.0	89.7	90.3	90.5	90.8	90.8	90.0	90.7
Underground output mechanically loaded net tons	186,667,250	232,902,920	249,805,214	274,189,132	262,512,729	245,340,768	298,157,281	295,806,285
Percent of underground output mechanically loaded	40.7	45.2	48.9	52.9	56.1	58.4	60.7	64.3
Quantity mined by stripping net tons	55,071,609	67,202,663	79,685,175	100,898,376	109,986,865	112,963,717	139,395,011	139,505,920
Percent mined by stripping	10.7	11.5	13.5	16.3	19.0	21.1	22.1	23.3
Quantity cleaned by wet or pneumatic process [4] net tons	117,539,522	142,187,346	145,575,849	158,727,129	147,885,936	138,669,837	174,435,937	180,880,323
Percent cleaned by wet or pneumatic process [4]	22.9	24.4	24.7	25.6	25.6	26.0	27.7	30.2

[1] Includes coal trucked to railroad for further shipment.
[2] Includes coal trucked to waterway for further shipment.
[3] Average number of men working daily.
[4] Includes central washeries operated by consumers.

TABLE 12.—Coal produced in the United States, by States, 1939–48 with production of maximum year and cumulative production from earliest record to end of 1948, in thousands of net tons

State	Maximum production		Production by years										Total production from earliest record to end of 1948
	Year	Quantity	1939	1940	1941	1942	1943	1944	1945	1946	1947	1948

1948	217	[6] 16	6.26	1,358	90.7	64.3	30.2	23.3

[2] Data not available.
[4] Percentages for 1890 to 1912, inclusive, are of total production, as a separation of strip and underground production is not available for those years.
[5] For 1906 to 1926, inclusive, these percentages are exclusive of coal cleaned at central washeries operated by consumers.
[6] Bureau of Labor Statistics, U. S. Department of Labor.

TABLE 14.—Growth of strip mining at bituminous-coal and lignite mines in the United States, 1914–48

Year	Production (thousand net tons)			Percent of total mined by stripping	Average tons per man per day			Average value per ton, f. o. b. mine			Number of strip mines	Number of power shovels and draglines
	Strip mines	Under-ground mines	Total		Strip mines [1]	Under-ground mines [2]	Total	Strip mines [1]	Under-ground mines [2]	Total		
1914	1,281	421,423	422,704	0.3	5.06	3.71	3.71	(3)	(3)	$1.17	[4] 35	48

[1] Includes power strip pits proper and excludes horse stripping operations and mines combining stripping and underground in the same operation for the years 1914–42, inclusive. The years 1943–48, inclusive, include data, on all strip mines.

[2] Computed by deducting "Strip mines" data from "Total."

[3] Data not available.

[4] Exclusive of horse stripping operations.

TABLE 15.—Growth of mechanical loading at underground bituminous-coal and lignite mines in the United States, 1923–48

[Production in thousands of net tons]

Year	Underground production mechanically loaded: Loaded by machines: Mobile loading machines	Loaded by machines: Scrapers	Loaded by machines: Conveyors equipped with duck-bills or other self-loading heads	Loaded by machines: Total	Handled by conveyors: Pit-car loaders	Handled by conveyors: Hand-loaded conveyors	Handled by conveyors: Total	Total mechanically loaded	Total underground production	Percent of underground production mechanically loaded	Number of mechanical loading units in actual use: Mobile loading machines	Scrapers	Conveyors equipped with duck-bills or other self-loading heads	Pit-car loaders	Hand-loaded conveyors	Total all types

[1] Includes coal loaded at mine directly into railroad cars or river barges.

[2] Includes coal used by mine employees, taken by locomotive tenders at tipple, used at mine for power and heat, coal transported from mine to point of use by conveyor or tram, coal made into beehive coke at mine, and all other uses at mine.

[3] Value received or charged for coal, f. o. b. mine, including selling cost. (Includes a value for coal not sold but used by producer, such as mine fuel and coal coked [not coke] as estimated by producer at average prices that might have been received if such coal had been sold commercially.)

PRODUCTION BY WEEKS AND MONTHS

TABLE 19.—Bituminous-coal and lignite production (final figures) in the United States in 1948, with estimates by weeks

Week ended—	Production (net tons)	Number of working days	Average production per working day (net tons)	Week ended—	Production (net tons)	Number of working days	Average production per working day (net tons)

TABLE 21.—Coal production in the United States in 1948, by States (final figures), with estimates by months, in thousands of net tons

[Totals for year are based on final complete returns from all operators known to have produced 1,000 tons and over per year. In most cases monthly apportionment is based on current records of railway carloadings and waterway shipments; in some States upon direct tonnage reports by operators to State mine departments]

[1] Revised figure.

MINE SIZE AND MECHANIZATION

Production at strip mines and underground mines with mechanical loading increased sharply in the period 1938–47. (See fig. 10.) A great majority of the small mines employ 100 percent hand loading. Figure 11 shows percentage of output classified by size of mines and methods of mining in 1947. Weekly Coal Report 1657 Supplement (June 17, 1949) shows detailed data of bituminous-coal and lignite mines by type of mining and underground loading and size of mines, by States, in 1947.

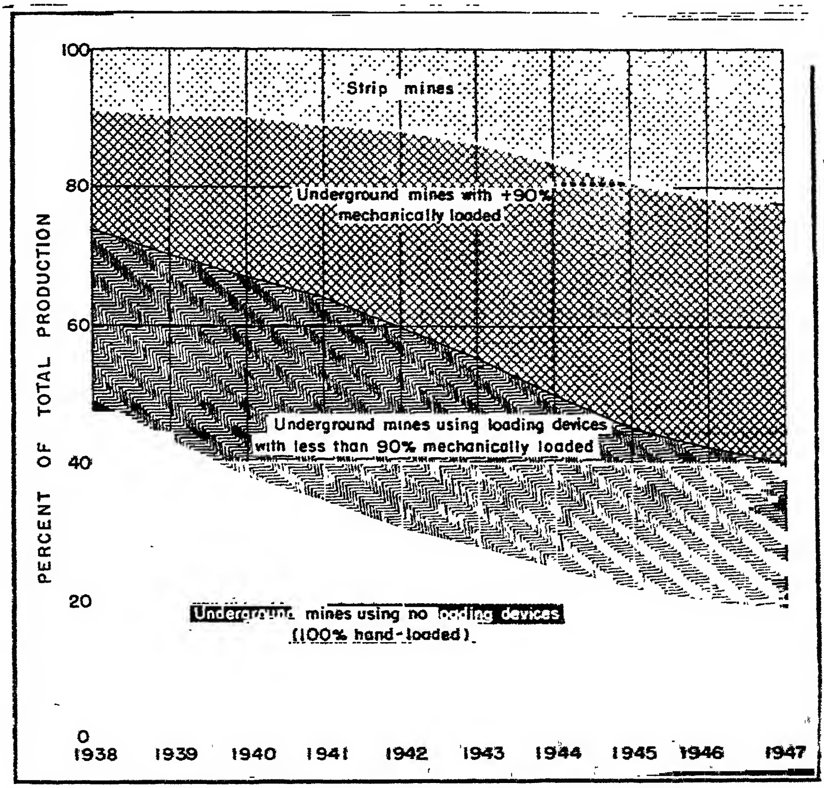

FIGURE 10.—Bituminous-coal and lignite production in the United States, by methods of mining, 1938–47.

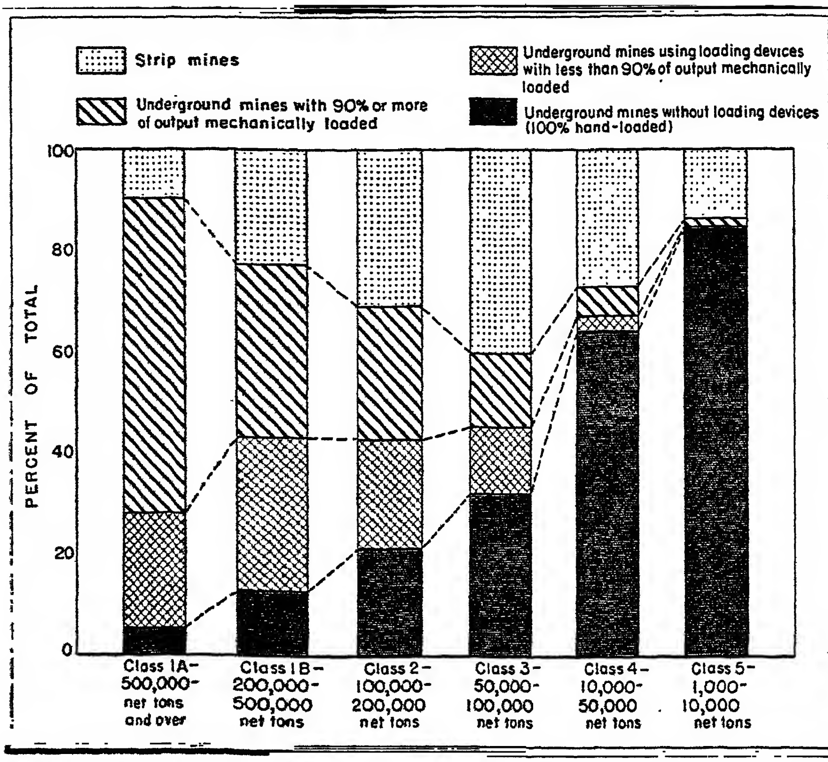

FIGURE 11.—Percentage of bituminous-coal and lignite production in the United States, classified by size of mines and method of mining, in 1947.

MECHANICAL LOADING

Bituminous coal and lignite mechanically loaded in underground mines amounted to 295,806,285 tons in 1948, or 64 percent of the total underground output.

Mechanical loading equipment used in underground bituminous-coal and lignite mines is divided into two types: Devices that virtually eliminate hand shoveling (known as mobile loaders, scrapers, and self-loading conveyors) and those that greatly reduce the labor in hand shoveling (known as hand-loaded face conveyors and pit-car loaders). Devices in the first category are designated "machines" and those in the second category, "conveyors."

A few continuous miners were used in 1948. They are included with mobile loaders in the following tables.

Sales of Mechanical Loading Equipment.—Shipments of mechanical loading equipment for underground use in coal mines in the United States, in terms of capacity, were less in 1949 than in any year since 1935. Table 27 shows the sales of loading equipment reported to bituminous coal and lignite operators, by type of equipment, and the number of manufacturers reporting for 1942–49.

Table 29 compares loading equipment, "mother" conveyors, and shuttle cars in use in bituminous-coal and lignite mines with sales in 1949, by States.

Extent of Mechanical Loading.—More than 78 percent of the underground mechanically loaded tonnage was handled by mobile loaders in 1948. Table 30 shows the tons and percent handled by each type of equipment in 1947 and 1948.

During 1948, in underground bituminous-coal and lignite mines, 3,980 mobile loaders handled 232,667,172 tons, an average of 58,459 tons per mobile loader per year; self-loading conveyors averaged 12,030; scrapers, 13,272; hand-loaded face conveyors, 10,322; and pit-car loaders, 4,971 per unit per year.

Mechanical Loading by States.—West Virginia has been the leading producer of mechanically loaded coal since 1939. During 1948 West Virginia produced 103,755,282 tons of mechanically loaded coal, followed by Pennsylvania with 53,498,497, Illinois with 43,042,416, Kentucky with 31,569,643, and Ohio with 13,389,427 tons. These five States produced 83 percent of the total output of underground mechanically loaded bituminous coal in the United States in 1948.

Detailed data, by States, on the number of mines and machines and the production of mechanically loaded coal compared with the total production at mines using mechanical loading devices are given in table 31. Comparative changes in underground mechanical loading in 1947–48, by States, are shown in table 32.

Table 33 shows bituminous-coal and lignite tonnage mined by stripping, compared with underground hand-loaded and machine-loaded tonnage, also productivity at strip and underground mines, by States, for 1948.

TABLE 27.—Units of mechanical loading equipment sold to bituminous-coal and lignite mines for underground use in the United States, as reported by manufacturers, 1942–49

Type of equipment	1942	1943	1944	1945	1946	1947	1948	1949	Change 1949 from 1948 (percent)

MECHANICAL CLEANING

Bituminous coal mechanically cleaned in 1948 amounted to 180,880,323 tons, or 30 percent of the total output.

Mechanical cleaning by wet methods includes jigs, concentrating tables, classifiers, launders, dense-medium processes, and any combinations of these five methods.

Pneumatic methods of coal cleaning include air tables, air flow, air sand, and any combination of these three methods.

Tables 34, 35, 38, and 39 include mechanical-cleaning data on all coal mined in the United States except Pennsylvania anthracite. Tables 36 and 37 are on the same basis but do not include consumer-operated plants. There are no mechanical cleaning plants at lignite mines.

Consumer-operated plants include plants owned by steel companies that receive coal (usually from affiliated companies), clean it, and then consume it directly at the plant.

Types of Cleaning Equipment.—The tonnage of bituminous coal cleaned by wet-washing methods was 164,664,522 tons in 1948—an increase of 6 percent over 1947. The quantity cleaned by pneumatic methods was 16,215,801 tons—a decrease of 12 percent.

Table 35 compares the number of cleaning plants and the tons of cleaned coal, by types of equipment, for 1947 and 1948. During 1948, 482 wet-washing and 84 pneumatic cleaning plants were in operation. Sixty-four tipples used both wet and dry methods at the same plant; deducting these duplications gives a net total of 502 plants that cleaned coal in 1948, an increase of 41 plants over 1947.

Mines served by cleaning plants (exclusive of those that ship to washeries operated by steel companies) produced 251,711,541 tons, or 42 percent of the total bituminous output in 1948. In this same group of mines, 170,478,391 tons were cleaned mechanically; therefore, 68 percent of the coal produced at mines with cleaning plants in 1948 was cleaned at the mine. The remainder of the output from these mines (32 percent) presumably represents the larger sizes commonly picked by hand. (See tables 37 and 39.)

Relation Between Raw Coal, Clean Coal, and Refuse.—For every 100 tons of raw coal cleaned during 1948 at the mines, 84 tons of clean merchantable coal, on an average, were obtained, and 16 tons of refuse were discarded. Table 39 shows total production of mines with cleaning plants and results of cleaning operations, by States.

Methods of Mining at Mines Served by Cleaning Plants.—Underground mechanical loading appears to be closely related to mechanical cleaning. Underground coal loaded mechanically in 1948 totaled 295,806,285 tons, of which 171,345,813 tons (58 percent) passed through tipples equipped with mechanical cleaning devices. Production of coal from strip mines in 1948 was 139,505,920 tons, of which 44,304,574 tons (32 percent) came from strip mines having mechanical cleaning tipples. Hand-loaded underground coal production in 1948 totaled 164,206,024 tons, of which 22 percent passed through tipples equipped with cleaning plants. (See tables 33 and 37.)

Historical Data on Mechanical Cleaning.—Table 16 shows data on bituminous coal cleaned by types of equipment, 1927-48, inclusive.

Data on method of mining at bituminous-coal mines served by cleaning plants, for the years 1933–48, are given in table 17.

TABLE 34.—Bituminous coal mechanically cleaned by wet and pneumatic methods, in the United States, in net tons of clean coal, 1945–48

Method of cleaning	1945	1946	1947	1948	Change 1948 from 1947 (percent)
Wet methods:					
At mines	121,418,585	115,120,292	145,958,413	154,262,590	+5.7
At consumer-operated cleaning plants	9,051,154	6,938,347	10,125,039	10,401,932	+2.7

Grand total	[1] 524	[1] 566	174,435,937	180,880,323	100.0	100.0

[1] Number of plants using both wet and pneumatic methods was 63 in 1947 and 64 in 1948.

TABLE 36.—Total production of all coal at bituminous mines in the United States having cleaning plants, 1947–48, in net tons

[Does not include estimates for mines that may ship to consumer-operated plants]

Type of equipment	1947	1948	Change 1948 from 1947 (percent)
Wet methods:			
Jigs	123,267,688	127,475,329	+3.4
Concentrating tables	945,919	1,659,611	+75.4
Classifiers	33,176,301	35,275,913	+6.3
Launders	19,721,354	16,000,190	−18.9
Dense-media	34,901,017	40,965,796	+17.4
Jigs and concentrating tables	4,697,185	5,552,845	+18.2
Other combinations of above methods	17,953,150	16,929,753	−5.7
Total wet methods	234,662,614	243,859,437	+3.9
Pneumatic methods	59,917,199	56,288,590	−6.1
Grand total	294,579,813	300,148,027	+1.9
Less duplications [1]	50,068,272	48,436,486	−3.3
Net total	244,511,541	251,711,541	+2.9
United States total production [2]	630,623,722	599,518,229	−4.9
Percent produced at mines having cleaning plants	38.8	42.0	

[1] Mines using both wet and pneumatic methods.
[2] Includes all coal except Pennsylvania anthracite. There are no mechanical cleaning plants at lignite mines.

TABLE 37.—Total production from bituminous-coal mines served by cleaning plants, by method of mining, 1945–48

[Does not include estimates for mines that may ship to consumer-operated plants]

Method of mining	1945		1946		1947		1948	
	Thousand tons	Percent	Thousand tons	Percent	Thousand tons	Percent	Thousand tons	Percent
Mined from strip pits	35,910	16.8	33,222	16.6	42,016	17.2	44,305	17.6
Mechanically loaded underground	129,733	60.5	125,521	62.7	158,507	64.8	171,346	68.1
Hand-loaded underground	48,615	22.7	41,531	20.7	43,988	18.0	36,061	14.3
Total	214,258	100.0	200,274	100.0	244,511	100.0	251,712	100.0

TABLE 38.—Bituminous coal mechanically cleaned by wet and pneumatic methods in the United States, by States, 1947–48

[Coal cleaned and plants operated by consumers at central washeries in Colorado and Pennsylvania included]

State	Plants in operation		Net tons of clean coal		Output mechanically cleaned (percent)	
	1947	1948	1947	1948	1947	1948
Alabama	52	55	13,923,152	13,463,049	73.1	71.6
Alaska	1	1	171,799	147,360	47.6	36.1
Arkansas	4	4	250,060	134,569	13.4	8.1
Colorado	8	8	1,373,708	1,530,318	21.6	27.2
Illinois	53	55	33,363,568	34,619,845	49.2	53.0
Indiana	22	22	13,865,723	13,530,612	54.5	56.7
Kansas	4	3	1,349,393	1,191,344	49.2	46.9

Pennsylvania [1]	62	66	36,728,026	35,602,133	25.0	26.5
Tennessee	3	3	188,572	266,900	3.0	4.1
Utah	3	5	1,679,577	2,134,386	22.6	31.3
Virginia	18	21	3,375,524	4,098,567	16.7	22.8
Washington	19	20	954,734	1,055,749	85.4	86.5
West Virginia [2]	148	165	41,227,011	46,376,742	23.4	27.5
Total	[3] 461	[4] 502	174,435,937	180,880,323	27.7	30.2

[1] Includes some coal mined in Pennsylvania and cleaned in Ohio and a small tonnage mined in other States and cleaned at a consumer-operated plant in Pennsylvania.
[2] Includes some coal mined in West Virginia and cleaned in Ohio and Pennsylvania.
[3] Represents 63 plants using both wet and pneumatic methods of cleaning and 398 plants using only 1 cleaning method.
[4] Represents 64 plants using both wet and pneumatic methods of cleaning and 438 plants using only 1 cleaning method.

TABLE 39.—Result of operations at bituminous-coal-cleaning plants in the United States, by States, in net tons, in 1948

State	Total raw coal moved to cleaning plants	Coal obtained in cleaning process	Refuse resulting in cleaning process	Ratio of refuse to raw coal (percent) [1]	Total production from mines served by cleaning plants
Alabama	18,178,213	13,463,049	4,715,164	25.9	14,350,310
Alaska	211,360	147,360	64,000	30.3	147,360

Virginia	4,597,293	4,098,567	498,726	10.8	8,991,323
Washington	1,307,423	1,055,749	251,674	19.2	1,113,343
West Virginia [3]	52,799,266	46,376,742	6,422,524	12.2	82,569,168
Total at mines only [4]	203,692,704	170,478,391	33,214,313	16.3	251,711,541
Consumer plants [5]	11,524,467	10,401,932	1,122,535	9.7	----------
Grand total 1948	215,217,171	180,880,323	34,336,848	16.0	----------

[1] In Alabama (for example) for every 100 tons of raw coal cleaned in 1948, an average of 25.9 tons of refuse was discarded and 74.1 tons of clean marketable coal was obtained.
[2] Includes some coal that was mined in Pennsylvania and cleaned in Ohio.
[3] Includes some coal that was mined in West Virginia and cleaned in Ohio and Pennsylvania.
[4] Includes all mechanical cleaning other than washeries operated by consumer steel companies.
[5] Includes central washeries in Colorado and Pennsylvania operated by consumer steel companies.

DETAILED STATISTICS, BY STATES AND COUNTIES

Detailed production and employment statistics are given in table 40 for each coal-producing county in the United States from which three or more operators submitted reports for 1948. Statistics on counties with less than three reporting producers have been combined with data for other counties in the same State to avoid disclosing individual figures, unless the operators have granted permission to publish them separately. Production of mines on the border between two States has been credited to the State from which the coal was extracted rather than to that in which the tipple was situated. If the coal is mined from lands in both States, the tonnage has been apportioned accordingly.

The data in the present report, as in those published for many years by the Bureau of Mines, relate only to mines with an annual output of 1,000 tons or more. That fact should be borne in mind when the statistics in this report are compared with similar data compiled by State mine departments. Differences arise largely from variations in coverage by State reports, some of which include data for all mines regardless of size, and others only data for mines employing more than a specified minimum number, ranging from 2 to 10 men.

Because of a change in method of reporting, beginning with 1946, statistics of average production per man per day are not precisely comparable with those for other years. The figures since 1946 were based on the average number of men working daily, whereas the figures for previous years were based on the average number of men on the rolls per pay period.

TABLE 40.—Production, value, employment, days active, man-days, and output per man per day at bituminous-coal and lignite mines in the United States, by States and counties, in 1948

[Exclusive of mines producing less than 1,000 tons]

County	Production (net tons)				Average value per ton [3]	Average number of men working daily				Average number of days mines were active	Number of man-days worked	Average tons per man per day [4]

[1] Includes coal loaded at mine directly into railroad cars or river barges, hauled by truck to railroad siding, and hauled by truck to waterway.
[2] Includes coal used by mine employees, taken by locomotive tenders at tipple, used at mine for power and heat, coal transported from mine to point of use by conveyor or tram, coal made into beehive coke at mine, and all other uses at mine.
[3] Value received or charged for coal, f. o. b. mine, including selling cost. (Includes a value for coal not sold but used by producer, such as mine fuel and coal coked [not coke] as estimated by producer at average prices that might have been received if such coal had been sold commercially.)
[4] In certain counties the average tons per man per day is large due to strip mining or mechanical loading underground.

Total loaded at mines for shipment by railroads and waterways		524,928,663	524,928,663
Shipped by truck		58,260,427	58,260,427
Used at mine [2]		16,329,129	16,329,129
Total production 1948		599,518,219	599,518,219

[1] Includes coal loaded at mine directly into railroad cars or river barges, hauled by truck to railroad siding and hauled by truck to waterway. In general, figures show the quantity of bituminous coal and lignite originated for each railroad and waterway as reported by mine operators. It must be noted that in one year an operator may report coal loaded on the subsidiary railroad and in another year the same operator may report coal loaded on the parent railroad system.

[2] Includes coal used by mine employees, taken by locomotive tenders at tipple, used at mine for power and heat, coal transported from mine to point of use by conveyor or tram, coal made into beehive coke at mine, and all other uses at mine.

STATISTICS ON LIGNITE IN 1948 [3]

According to reports received by the Bureau of Mines, the production of lignite in the United States in 1948 (exclusive of small mines producing less than 1,000 tons) totaled 3,085,886 net tons, an increase of 7 percent over 1947, and the highest production since 1937. The average value increased from $1.92 per ton in 1947 to $2.27 in 1948. The average number of men employed totaled 694, a slight decline from the 747 men working in 1947, and the output per man per day (based upon calculated man-days) was 17.53 tons in 1948. The industry worked an average of 254 days in 1948, compared with 250 in the preceding year. North Dakota produced 96 percent of the total lignite mined in the United States; California, Montana, South Dakota, and Texas, together accounted for the remaining 4 percent.

According to the Federal Power Commission, 1,150,716 tons of lignite were consumed in generating electric energy in 1948; this amounts to 37 percent of the total lignite mined in the United States in that year. Consumption in the West North Central States was 1,121,853 tons; the West South Central and Mountain States consumed 28,863 tons.

All data are submitted on a voluntary basis by producers of lignite, and the Bureau of Mines wishes to thank them for their cooperation in supplying the data, without which this report would not have been possible.

TABLE 42.—Summary of production, value, employment, days operated, man-days of labor, and output per man per day at lignite mines in the United States in 1948, by States [1]

	California	Montana [2]	North Dakota	South Dakota	Texas	Total
Production (net tons):						
Loaded at mines for shipment			2,406,919	7,996	56,693	2,471,608

[1] Output is obtained chiefly from strip pits in which the production per man per day is large.

In 1948, the Bureau of Mines received reports from 52 lignite mines producing 1,000 tons or more annually. Seven mines produced over 100,000 tons, and the output of these mines amounted to 82 percent of the total production, 4 reported production of 50,000 to 100,000 tons each and accounted for 8 percent of the total, and 41 mines producing less than 50,000 tons accounted for 10 percent of the total.

TABLE 44.—Number and production of lignite mines in the United States in 1948, classified by size of output

Class	Mines		Production		
			Net tons		Percent of total
	Number	Percent	Total	Average per mine	
100,000 tons and over	7	13.5	2,530,397	361,485	82
50,000 and under 100,000	4	8	262,207	65,552	8
10,000 and under 50,000	7	13.5	142,840	20,406	5
Under 10,000 tons	34	65	150,442	4,425	5
Total	52	100	3,085,886	59,344	100

TABLE 45.—Lignite mined by different methods in the United States in 1948, by States, in net tons

Method	California	Montana	North Dakota	South Dakota	Texas	Total
From underground workings:						
Shot off the solid		36,081	23,036			59,117
Cut by machines [1]			461,795			461,795
Total underground		36,081	484,831			520,912
From strip pits	1,450	1,579	2,476,158	29,094	56,693	2,564,974
Grand total production	1,450	37,660	2,960,989	29,094	56,693	3,085,886

[1] A total of 6 machines was used—1 "permissible" and 5 other types.

The production of lignite from strip pits amounts to 2,564,974 tons—83 percent of the total output of the industry. North Dakota produced 97 percent of the lignite mined by this method; the output of lignite from stripping operations for the other four States amounted to only 88,816 tons.

TABLE 46.—Summary of stripping operations that produced lignite in the United States in 1948, by States

	California	Montana	North Dakota	South Dakota	Texas	Total
Number of strip pits [1]	1	1	30	2	1	35
Number of shovels, dragline excavators, and coal-loading machines [2]			44	2	1	47
Coal produced by stripping	1,450	1,579	2,476,158	29,094	56,693	2,564,974
Total production value at mines	$14,500	$4,737	$5,706,679	$86,208	$58,034	$5,870,158
Average value per ton	$10.00	$3.00	$2.30	$2.96	$1.02	$2.29
Number of employees:						
In strip pits	4	2	239	16	10	271
All others		2	195	2	6	205
Total	4	4	434	18	16	476
Average number of days mines operated	82	43	258	212	265	254
Man-days of labor	328	172	112,125	3,820	4,240	120,685
Average tons per man per day	4.42	9.18	22.08	7.62	13.37	21.25

[1] Includes some pits in which stripping is done by hand.
[2] In some cases the same equipment was used for stripping or excavating and for loading coal; this duplication has been eliminated. In some cases coal was excavated by machine and loaded by hand.

Dakota	23,392	36,373	50,210
Duluth and Superior	385,936	340,995	204,062
Michigan	3,046,644	3,127,640	2,245,509
Montana and Idaho	4,431	723	1,284
Ohio	11,619,905	13,314,027	8,763,969
Rochester	3,839,918	3,465,712	1,795,570
St. Lawrence	3,677,266	2,815,519	1,473,782
Vermont	4,106	5,041	1,575
Wisconsin	193		
Miscellaneous	18,663	283	84
Total	[2] 68,666,963	[2] 45,930,133	[2] 27,842,066

[1] Revised figure.
[2] Includes 192,905 tons in 1947, 434,070 tons in 1948, and 277,555 tons in 1949, representing shipments on vessels operated by the United States Army or Navy. Excludes 102,179 tons exported to Austria in 1947 as a part of the Army Civilian Supply Program.

TABLE 51.—Shipments of bituminous coal to noncontiguous Territories, 1947–49

[U. S. Department of Commerce]

Territory	1947		1948		1949	
	Net tons	Value	Net tons	Value	Net tons	Value
Alaska [1]	6,860	$112,272	(2)	(2)	(2)	(2)
Hawaii	365	10,135	(2)	(2)	(2)	(2)
Puerto Rico	9,148	78,593	1,500	$15,607	4,999	$48,366
Virgin Islands	44,514	334,149	25,799	264,564	20,601	196,211

[1] Includes shipments of anthracite.
[2] Beginning Apr. 1, 1948, no data available.

WORLD PRODUCTION

TABLE 52.—World production of coal and lignite, by countries, 1942–49, in thousands of metric tons [1]

TABLE 52.—World production of coal and lignite by countries, 1942–49 in thousands of metric tons [1]—Continued

Country [1]	1942	1943	1944	1945	1946	1947	1948	1949
Oceania:								
Australia:								
New South Wales	12,433	11,714	11,280	10,402	11,397	11,896	11,909	10,910
Queensland	1,663	1,727	1,686	1,661	1,593	1,914	1,770	[22] 1,352
South Australia	2		35	42	138	196	243	[22] 280
Tasmania	137	148	146	151	161	170	182	[22] 126
Victoria:								
Coal	318	292	262	251	194	176	170	[22] 84
Lignite	5,013	5,173	5,097	5,533	5,799	6,239	6,800	[22] 5,713
Western Australia	591	540	567	552	653	742	745	764
New Zealand:								
Coal	1,194	1,157	1,085	980	974	951	968	937
Lignite	1,529	1,676	1,766	1,899	1,865	1,845	1,853	1,874
Total, all grades	1,874,000	1,838,000	1,765,000	1,338,000	1,477,000	1,649,000	1,706,000	1,632,000
Lignite (total of items shown above)	313,000	328,000	309,000	168,000	222,000	238,000	246,000	263,000
Bituminous coal and anthracite (by subtraction)	1,561,000	1,510,000	1,456,000	1,170,000	1,255,000	1,411,000	1,460,000	1,369,000

[1] Coal is also mined in British Borneo, Faroe Islands, and Italian East Africa (formerly), but production figures are not available and no estimate is included in the total.
[2] A change from previous years has been made in the classification adopted by the American Society for Testing Materials. (Alberta is the only Province affected.)
[3] Data not available; estimate included in total.
[4] Estimate.
[5] In addition, the following quantities (metric tons) of asphaltite were produced and used as solid fuels: 1942, 56,387; 1943, 105,625; 1944, 106,300; 1945, 135,300; 1946, 83,800; 1947, 80,900; 1948 and 1949, data not available.
[6] July to December, inclusive.
[7] Data represent Trianon Hungary subsequent to October 1944.
[8] January to October, inclusive.
[9] Includes that part of Germany which is under Polish administration (east of the Oder and Neisse Rivers).
[10] Includes open-cast coal as follows, in thousands of tons: 1942, 1,332; 1943, 4,498; 1944, 8,787; 1945, 8,246; 1946, 8,965; 1947, 10,407; 1948, 11,916; 1949, 12,599.
[11] Production less than 1,000 tons.
[12] Estimated production of Croatia.
[13] January to June, inclusive.
[14] Excludes production of Ombilin mines in Sumatra.
[15] Fiscal year ended Mar. 20 of year following that stated.
[16] Fiscal year ended Mar. 31 of year following that stated.
[17] Included under India.
[18] Output from U. S. S. R. in Asia included with U. S. S. R. in Europe.
[19] Planned production.
[20] Including British Cameroons.
[21] Local sales and exports.
[22] January to September, inclusive.

Coal—Pennsylvania Anthracite

By J. A. Corgan and Marian I. Cooke

GENERAL SUMMARY

BECAUSE anthracite is primarily a space-heating fuel, the over-all annual consumption is affected directly by the intensity of the weather. Abnormally warm weather was one of the most important contributing factors in the sharp decline in the 1949 production of Pennsylvania anthracite to 42,701,724 net tons, a 25-percent decrease from 1948. Other important factors contributing to the drop in output were competition from other fuels, especially fuel oil and natural gas, and loss in foreign markets. With increased output of coal in Europe, those countries were in a better position to supply their own fuel needs, and Canada's requirements dropped commensurately with the extremely warm weather of the 1949 winter months.

The various types of mining contributed virtually the same proportions in 1949 as in 1948. Output from deep mines accounted for 63 percent of the 1949 production; strip pits, 24 percent; and culm banks, 11 percent. Dredging operations, which normally represent only a small part of the over-all annual output of anthracite, supplied 2 percent of the total output in 1949. Although the average number of men employed dropped to 75,377, a slight decline from 1948, the output per man per day, which averaged 2.81 tons in 1948, increased to 2.87 tons in 1949. The mines worked an average of 195 days compared with 265 days in 1948.

The New England and Middle Atlantic States, Maryland, Delaware, and the District of Columbia received 87 percent of the total anthracite shipments in 1949. Other States received 3 percent, and shipments to Canada and other foreign countries totaled 10 percent.

The mine workers received substantial wage increases and other benefits under a new wage contract between the anthracite producers and the United Mine Workers of America which became effective March 16, 1950; the contract will terminate June 30, 1952.

Statistical Trends—Tables 1 and 2 present pertinent statistical data on the Pennsylvania anthracite industry.

Anthracite Committee.—The Anthracite Committee continued its regular activities pertaining to the collection of data on employment, production, and requirements of anthracite and in addition kept the industry informed regarding "bootleg" mining activities. The committee is the only agency having complete and accurate statistics concerning the so-called bootleg mining industry, which in 1949 produced 1,257,218 net tons of anthracite. The committee continued its work regarding improvement in the quality of anthracite shipped from the mines. The Anthracite Standards Law approved May 31, 1947, was amended by the act of May 18, 1949, Public Law 437; the amendments became effective on September 1, 1949. This law applies to the sizes of anthracite commonly known as Broken, Egg, Stove,

TABLE 1.—Salient statistics of Pennsylvania anthracite industry, 1945–49

	1945	1946	1947	1948	1949
Production:					
Loaded at mines for shipment:					
Breakers net tons	[1] 45,249,706	50,115,427	[1] 48,073,153	47,816,627	35,653,628

Chestnut, Pea, Buckwheat No. 1, and Buckwheat No. 2 (Rice) and fixes certain standards for these sizes, including the maximum amount of ash content and of undersize permitted or, as regards Broken, Egg, Stove, Chestnut, and Pea sizes, the maximum percentage of slate and bone. Anthracite that conforms to the standards fixed by the act is standard anthracite; that which does not conform is called substandard anthracite. On and after September 1, 1949, all anthracite of the sizes referred to above which is produced in Pennsylvania must be attested by the producer as either standard anthracite or substandard anthracite, whether shipped to a point within or without the State. Standard anthracite specifications approved and adopted by the Anthracite Committee are shown in table 3.

Anthracite Institute.—In 1949 the Anthracite Institute continued the large industry advertising and promotional campaign started in 1948, in order to sell the advantages of anthracite and anthracite-burning equipment to the public. Consumer advertisements were run in leading newspapers of the anthracite-marketing area; these were supplemented by magazine and trade periodical advertising. In addition, over-all industry advertising was augmented by several

TABLE 2.—Statistical summary of monthly developments in the Pennsylvania anthracite industry in 1949

[All tonnage figures represent net tons]

	January	February	March	April	May	June	July	August	September	October	November	December	Total 1949	Change from 1948 (percent)	Total 1948

[1] Furnished by Anthracite Institute.
[2] Pennsylvania Department of Mines.
[3] Association of American Railroads.
[4] Ore and Coal Exchange, Cleveland, Ohio.
[5] Buffalo Branch, Ore and Coal Exchange, Cleveland, Ohio.
[6] U. S. Engineer Office, Duluth, Minn.
[7] Includes all commercial docks on Lake Superior and west shore of Lake Michigan as far south as Kenosha. Based on data courteously supplied by Maher Coal Bureau and direct reports to the Bureau of Mines.
[8] Furnished by Commonwealth of Massachusetts, Division on the Necessaries of Life.
[9] U. S. Department of Commerce.
[10] Federal Power Commission.
[11] Anthracite Committee. Represents coal in storage nearest available date to the end of the month.
[12] Bureau of Labor Statistics.

TABLE 3.—Standard anthracite specifications approved and adopted by the Anthracite Committee effective July 28, 1947

Percent

	Round test mesh, inches	Oversize, maximum	Undersize		Maximum, impurities [1]		
			Maximum	Minimum	Slate	Bone or ash [2]	
Broken	Through 4 3/8				1½	2	11
	Over 3¼ to 3		15	7½			
Egg	Through 3¼ to 3	5			1½	2	11
	Over 2 7/16		15	7½			
Stove	Through 2 7/16	7½			2	3	11
	Over 1 5/8		15	7½			
Chestnut	Through 1 5/8	7½			3	4	11
	Over 13/16		15	7½			
Pea	Through 13/16	10			4	5	12
	Over 9/16		15	7½			
Buckwheat No. 1	Through 9/16	10					13
	Over 5/16		15	7½			
Buckwheat No. 2 (Rice)	Through 5/16	10					13
	Over 3/16		17	7½			
Buckwheat No. 3 (Barley)	Through 3/16	10					15
	Over 3/32		20	10			
Buckwheat No. 4	Through 3/32	20					15
	Over 3/64		30	10			
Buckwheat No. 5	Through 3/64	30	No limit				16

[1] When slate content in the sizes from Broken to Chestnut, inclusive, is less than above standards, bone content may be increased by 1½ times the decrease in the slate content under the allowable limits, but slate content specified above shall not be exceeded in any event.

A tolerance of 1 percent is allowed on the maximum percentage of undersize and the maximum percentage of ash content.

The maximum percentage of undersize is applicable only to anthracite as it is produced at the preparation plant.

"Slate" is defined as any material which has less than 40 percent fixed carbon.

"Bone" is defined as any material which has 40 percent or more, but less than 75 percent fixed carbon.

[2] Ash determinations are on a dry basis.

outstanding campaigns of individual producing companies. Funds approved by the anthracite industry for use by the institute in 1950 call for the largest advertising and promotional campaign in anthracite's history. In 1949 the institute conducted anthracite stoker schools (using the audiovisual method of training) in 27 cities in the United States and 12 cities in Canada. The dealer training program, relating to the use of thermostats, stokers, heater conditioning, etc., was enlarged greatly in 1949, and further expansion will take place in 1950. The institute carried on extensive research into various phases of the utilization of anthracite. This research is discussed in some detail in this chapter under Research and Technology.

Labor Relations.—The Pennsylvania anthracite mines were closed for various reasons on several occasions in 1949. The United Mine Workers of America authorized a memorial period, March 14–28, in which the workers remained away from the mines; the union also called for a stabilizing period, June 13–20, and work ceased at the mines; another suspension occurred during the latter part of September over matters pertaining to the welfare fund; and effective Monday, December 5, and continuing to March 4, 1950, the United Mine Workers of America decided to work only 3 days a week. A new wage agreement was reached by the anthracite operators and the United Mine Workers on March 9, 1950, to supersede the amended contract of July 3, 1948. Substantial wage increases were received by the mine workers under the agreement, and the royalty on each ton of anthracite produced

was increased from 20 to 30 cents per ton. The contract called for the miners' 1950 vacation period to begin July 1 and end July 11; the vacation payment of $100 was continued. The agreement was effective as of March 16, 1950, and terminates June 30, 1952, provided, however, that either party may terminate the agreement on or after April 1, 1951, by giving at least 30 days' written notice to the other party of such desired earlier termination date.

Research and Technology.—In 1949 the Anthracite Flood Prevention Section of the Bureau of Mines continued to cooperate with the anthracite producers and the Commonwealth of Pennsylvania in obtaining information relating to the underground mine-water problem in the Pennsylvania anthracite region. Data of a technical nature have been evaluated, plans are being prepared to aid in solving the mine-water problem, and a number of reports covering various phases of this subject were prepared for publication. Bureau of Mines Report of Investigations 4656,[1] released in March 1950, gives data concerning the design and performance of deep-well and shaft pumps and their application to anthracite flood-prevention projects that can favorably use pumps of these types. The report includes a description of deep-well and shaft pumps in the anthracite area, data concerning their dependability, estimates of installation costs, and the general acceptance of the pumps by the anthracite producers. Bureau of Mines Bulletin 491 [2] presents a detailed report on the water problem of the Eastern Middle field. The inundated reserves in this field were studied with special reference to various methods by which the water could be removed economically from each of the pools in the field. The anthracite reserves have been depleted greatly in this area and by removing water in certain pools where it can be done economically, the life of the reserves will be extended and the future of the industry in this field brightened. Drainage tunnels are an important factor in removing water from the underground workings, and the report discusses this method of unwatering mines in some detail. Bureau of Mines Report of Investigations 4700 [3] furnishes detailed data on pumping practices which will be indispensable in solving the anthracite mine-water problem. The report includes a vicinity map showing the four anthracite fields; a description of horizontal centrifugal pumps, deep-well and shaft pumps, and plunger pumps; pictures of various mine-pumping-plant installations in the anthracite region, a map showing colliery-pumping stations and drainage tunnel discharge portals; and other technical data, including charts and graphs that concern the mine-water problem.

Virtual completion during the latter part of 1949 of the Bureau of Mines new research laboratory at Schuylkill Haven, Pa., is expected to speed the Bureau's research on mining, preparation, and utilization of anthracite. The Bureau is cooperating with anthracite producers in various mechanical mining studies whereby it is believed that the underground output per man per day may be increased. Considerable work has been done with air-powered German light-weight shearing

[3] Ash, S. H., Eaton, W. L., Gilbert, J. C., James, H. N., Jenkins, H. E., Kennedy, D. O., Kynor, H. D., Link, H. B., and Romischer, W. M., Pumping Data of the Anthracite Region of Pennsylvania: Bureau of Mines Rept. of Investigations 4700, 1950, 261 pp.

machines for use in both flat and pitching beds. Testing and experimental work is underway with a packing machine of German origin that has had widespread usage for many years on the Continent and in England. Experimental work was conducted in the design of a fully mechanized timbering method, whereby safety for face workers might be improved and heavy labor employed in conventional methods reduced.

The Anthracite Institute, at its laboratory in Wilkes-Barre, Pa., conducted extensive work on new and improved methods of burning anthracite in automatic coal-burning equipment. Research was continued on anthracite pellet production and the use of anthracite in fluid gas producers, and in curing tobacco.

The joint technical committee of the anthracite, bituminous, and coke industries continued its research on matters of interest to the three industries and stressed work on new ash-removal methods.

Research on anthracite conducted at the Pennsylvania State College over the past several years has covered a wide range of subjects, particular emphasis being placed on the upgrading and utilization of fine sizes of anthracite, the recovery and cleaning of fines by various processes, the use of anthracite as cupola fuel, the blending of anthracite fines with bituminous coal in producing coke, and the combustion and gasification of anthracite with regard to the flow of gases through coal beds of various sizes of anthracite.

The Eighth Annual Anthracite Conference met at Lehigh University, Bethlehem, Pa., in May 1950. Many excellent papers pertaining to anthracite research were presented.

Imports and Exports.—Exports of anthracite to foreign countries during 1949 were greater than in any year since 1923 with the exception of shipments during the postwar years 1946–48. The decline in exports in 1949 to 4,942,670 net tons from the total of 6,675,914 tons in 1948 was due largely to the sharp decrease in shipments to Canada. The abnormally warm weather in Canada during part of 1948 and the winter months of 1949 bore directly on the consumption of anthracite in that country and is believed to be the principal reason for the 27-percent decline in exports from the United States. One of the principal reasons for our greatly increased exports to Canada in recent years has been the inability of Great Britain to export anthracite to the Dominion in amounts approaching prewar levels. In 1949 Canada received 365,842 net tons of anthracite from Great Britain, compared with average annual shipments of about 1,200,000 tons before World War II. The decline in our export shipments to European countries—1,243,214 tons in 1949, compared with 1,692,967 in 1948 and 3,918,463 in 1947—may be attributed largely to increased output of coal in Great Britain, Poland, Germany, and France which enabled those countries in some instances to export coal to other European countries. France received 85 percent of the shipments to Europe in 1949, virtually all of which was Buckwheat No. 3 and smaller sizes of anthracite. Indications are that 1950 exports of anthracite to countries other than Canada will be negligible.

The total quantity of anthracite imported into the United States has been insignificant in recent years and constituted a very small part of our total consumption. There were no imports in 1949. Details of imports for 1947–48 are given in table 39.

SOURCES AND ACKNOWLEDGMENTS

Annual statistics of the Pennsylvania anthracite-mining industry are prepared from a canvass, by mail, of all known anthracite operations; about 99 percent of the tonnage is reported directly by producers, and the remaining 1 percent is estimated on collateral evidence. The data on individual operations furnished by the producers are voluntary and confidential, as is customary in the statistical services of the Bureau of Mines.

The standard form of report, as developed by the Bureau and its predecessor in mineral statistics, the Geological Survey, provides for data on production, shipments, mine realization of products, mechanization, plant and equipment, and employment.

In assembling available detailed information, free use has been made of the pertinent figures prepared by the Pennsylvania Department of Mines, the Anthracite Institute, the Anthracite Committee, and the Association of American Railroads, to all of whom thanks are extended for their cordial and continued cooperation. Thanks are due especially to the producers for reporting so promptly and, in general, so fully upon their operations in 1949, when the year as a whole was so critical for the industry.

PRODUCTION

The output of Pennsylvania anthracite in 1949 totaled 42,701,724 net tons, a sharp decline from the production of 57,139,948 tons in 1948. The decrease can be attributed to the impact on anthracite of competitive fuels, especially fuel oil and natural gas, and lessened consumption due to abnormally warm weather in the winter months of 1949. These statistics include deep-mined and strip-pit output, coal recovered from culm banks, anthracite purchased by the industry from "bootleggers," and river or creek coal recovered from the streams draining the anthracite fields. Also included is a small tonnage of semianthracite (20,090 tons in 1949) produced in Sullivan County.

In recent years conditions have favored development of numerous small mines operating on lease or subcontract and producing run-of-mine coal, which is sold to larger companies for preparation at a breaker. At the same time, an increasing transfer of coal from one operation to another has developed; and some of the companies have built central breakers to which coal from numerous mines is shipped, by rail or truck, for preparation. These tendencies have increased the complexity of the task of collecting and compiling statistics of the industry; but great care has been exercised to avoid double counting of tonnages produced by one operator and prepared for market by another. The figures herein represent the net quantity of merchantable coal plus the fuel used by the collieries themselves.

Prior to the early 1930's anthracite was produced only by concerns that owned or leased the coal lands; during the depression, however, unemployed miners began to mine anthracite in the Lehigh and Schuylkill regions from land of the operating companies and transported the coal to market by truck. Before 1941 this coal, generally

referred to as "bootleg" coal, was not included in the production statistics of the Pennsylvania anthracite industry compiled by the Bureau of Mines. In 1941, however, the anthracite industry began to purchase run-of-mine coal from the so-called bootleggers for preparation and shipment to market. In 1949 these purchases totaled 442,541 net tons. As it is impractical to segregate the purchased anthracite from the output of the industry proper, it is therefore included in the various production tables in the Minerals Yearbook chapters on Pennsylvania anthracite for 1941–49. To compute the output per man per day for the anthracite industry, it was necessary to deduct these purchases from the total tonnage shipped by the recognized industry, because adequate data on man-days required to produce the "bootleg" coal are not available. Details on this procedure are discussed in the Employment section of this chapter. See tables 4 to 9 for production and shipments by fields, regions, and counties. Tables 10 and 11 show percentages, by regions, of various sizes in relation to total breaker product.

TABLE 4.—Pennsylvania anthracite produced, 1945–49 by fields, in net tons

[The figures of breaker product include a certain quantity of culm-bank coal, which amounted to 3,013,712 tons in 1949]

[1] Value given for shipments is value at which coal left possession of producing company and does not include margins of separately incorporated sales companies.

[2] For purposes of historical comparison and statistical convenience, the mines of Sullivan County are grouped with the Pennsylvania anthracite region, although the product is classified as semianthracite according to the American Society for Testing Materials Tentative Standard.

By Weeks and Months.—Weekly production figures for anthracite as published in the regular weekly Anthracite and Beehive Coke reports are estimated from records of railroad carloadings and from reports obtained from trade sources. The weekly and monthly figures have been adjusted to the total annual anthracite production as obtained by a direct mail canvass of the operators. Tables 12 and 13 summarize weekly and monthly production of anthracite in 1949.

TABLE 12.—Estimated weekly production of Pennsylvania anthracite in 1949

Week ended—	Net tons	Week ended—	Net tons

Total	60,328	60,644	63,701	54,934	60,507	57,190	57,140	42,702

[1] Production is estimated from weekly carloadings as reported by the Association of American Railroads and includes mine fuel, coal sold locally, and dredge coal. Includes some "bootleg" coal purchased by legitimate operators and prepared at their breakers.

Culm-Bank Coal.—The recovery of coal from culm banks has been declining consistently since the peak of 9,600,180 tons reached in 1944; the production of 4,429,144 tons from this source in 1949 was a decline of 21 percent from the 1948 output and the lowest tonnage recovered from the banks since 1941. The culm banks in the anthracite region have been a source of coal supply for many years and were especially valuable during the coal shortages in World War II. However, coal available from this source is limited and it can be expected that the quantities recovered from the banks will decline from year to year. Tables 14 and 15 give details on production of anthracite from culm banks.

TABLE 14.—Production of Pennsylvania anthracite from culm banks, by regions, 1934–49, in net tons

Year	Lehigh	Schuylkill	Wyoming	Sullivan County	Total

[1] U. S. Department of Commerce.
[2] Prior to 1913 the figures of consumption take no account of producers' stocks, there being no data available for this item.
[3] Data first collected in 1911.
[4] Data first collected in 1915.
[5] Data first collected in 1929.
[6] As reported by the Commonwealth of Pennsylvania, Department of Mines.
[7] Data not available.
[8] Includes some "bootleg" coal purchased by legitimate operators and prepared at their breakers.
[9] Output per man per day calculated on legitimate tonnages only; "bootleg" purchases excluded.

"Bootleg" Coal.—According to the Anthracite Committee the production of so-called bootleg coal in 1949 totaled 1,257,218 tons, a substantial decline from the output of 1,839,227 tons reported in 1948. With the exception of the war year 1945, the output in 1949 from this source was the lowest since the depression years of the early 1930's. Although the output declined substantially in 1949 there was a 12-percent increase in both the number of active holes, and in the men employed, over 1948. A total of nine fatal accidents occurred in this type of mining in 1949. Details on "bootleg" mining for the period 1941–49 are given in tables 17 and 18.

VALUE OF SALES

Under the impact of higher costs of labor and materials, the average value per net ton of anthracite at the mines has been increasing consistently since 1939. The average sales realization per net ton on breaker shipments in 1949 was $8.90 compared with $8.67 in 1948; when colliery fuel, local sales, river coal, and washery coal are included, the average per ton value of the 1949 production is $8.38 compared with $8.17 in 1948. The average sales realization figures in this study represent value at the breaker, washery, or dredge, and the reporting company is asked to "exclude selling expenses"; therefore, when a producing company sells its output to a separately organized sales company, the value reported will exclude the margin of the sales company and may therefore be somewhat less than the circular price at which the coal is placed on the open market.

TABLE 19.—Average sales realization per net ton on Pennsylvania anthracite shipments from breakers, 1945–49, by regions and sizes

[Value does not include margins of separately incorporated sales companies]

Grand total	8.39	7.89	3.01	8.17	8.59	7.87	3.33	8.38

[1] Value given for shipments is value at which coal left possession of producing company and does not include margins of separately incorporated sales companies.

SHIPMENTS

The data shown in table 22 on the distribution of Pennsylvania anthracite are collected on a coal-year basis, as it more nearly corresponds with the heating season; therefore, no direct comparison is possible with annual statistics presented elsewhere in the chapter on production, method of movement, etc. The data were furnished voluntarily to the Bureau of Mines by producers, wholesalers, and dock operators and represent the seventh in a series of reports on the distribution of Pennsylvania anthracite.

Shipments of anthracite in the 1948–49 coal year totaled 48,407,035 net tons, as compared with 55,362,344 tons for the 1947–48 coal year. The decline was due largely to the fact that the winter of 1948–49 was one of the warmest on record, to competition of other fuels, and to a marked decrease in shipments to Europe. The Canadian market remained virtually unchanged, however, as is evidenced by the 4,389,355 net tons reported for the 1948–49 coal year. As indicated in the table, all consuming areas except the Lake States show a decline in tonnages received during the 1948–49 coal year; however, due to influence exerted by the drop in exports to Europe, the percentages shown for areas in the United States and Canada are higher than for the 1947–48 coal year.

1 Includes "Local sales."
2 Shipments to other States generally referred to as being in the South Atlantic area are included in "All other States."
3 Shipments to Indiana are included in "All other States."

According to data compiled from records of Pennsylvania State Department of Mines anthracite shipments from the mines to destinations in the United States declined 26 percent in 1949 as compared with 1948. In 1949, 82 percent of the shipments destined to points in this country moved from the mines by rail and 18 percent by truck, as compared to 83 and 17 percent, respectively, in 1948. Pennsylvania received 86 percent of the truck shipments in 1949, New Jersey 6 percent, and New York 7 percent. Anthracite rail shipments by States of destination for 1946–49 are shown in table 23 and the movement of anthracite by truck in 1949, by months and States of destination, in table 24.

Before 1948, the annual schedule of the Bureau of Mines covering production statistics of the anthracite industry has requested data for local sales only on total tonnages sold locally within the anthracite region. However, the Bureau received so many requests for local sales data on a size basis that it was deemed advisable to insert an item in the 1948 form requesting the industry to report local sales by sizes. The inclusion of size data for local sales in 1948 and 1949 makes the Bureau's production statistics on Pennsylvania anthracite much more complete than those of previous years. As indicated in the tables, sales of anthracite within the region totaled 3,848,420 tons in 1949.

According to data compiled from records of the Massachusetts Division on the Necessaries of Life and the Anthracite Emergency Tidewater Bureau rail receipts of Pennsylvania anthracite in New England decreased 28 percent from 1948; tidewater receipts decreased 49 percent. Details on anthracite movement to New England are given in table 25. Loadings at Lake Erie ports and receipts at upper Lake docks decreased 46 and 42 percent, respectively, from 1948. A large part of the decline in Lake Erie loadings in 1949 can be attributed to the decreased use of smaller steam sizes of anthracite by briquet manufacturers in the Great Lakes region.

[5] Less than 1,000 tons.

Shipments of anthracite from the Lehigh, Schuylkill, and Wyoming regions, 1890–1949, inclusive, are illustrated graphically in figure 1.

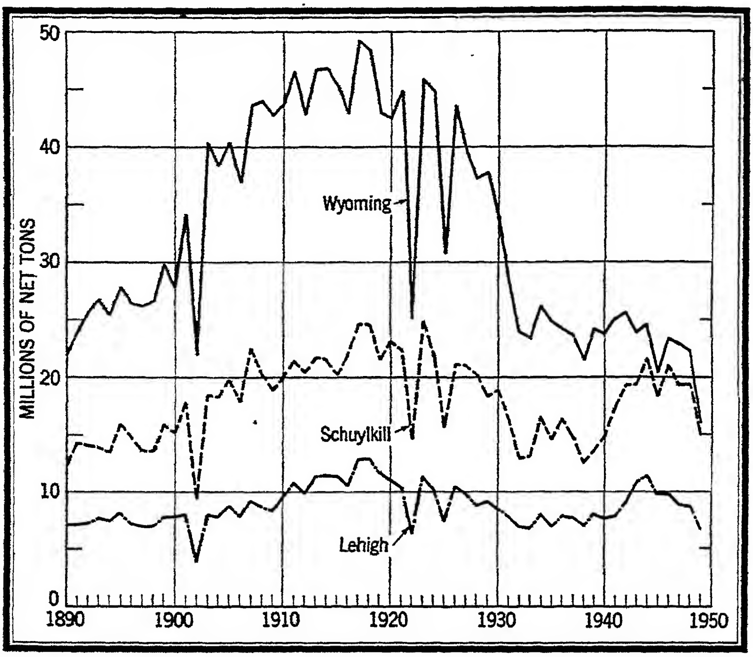

FIGURE 1.—Anthracite shipped from the Lehigh, Schuylkill, and Wyoming regions, 1890–1949.

CONSUMPTION

Anthracite is primarily a space-heating fuel, and the over-all consumption is related directly to the intensity of the weather. The winter months of 1949 were abnormally warm; this was responsible largely for the sharp decline in the apparent consumption of anthracite to 37,700,000 tons, a 25-percent decrease from 1948. Another important factor was, of course, the strong competition of natural gas and fuel oil. Apparent consumption is calculated on the basis of production, plus imports, minus exports, and changes in producers' stocks; but no attempt is made to reflect changes in retail dealers' stocks, as data for this group are incomplete. Consumption by class 1 railroads in 1949 totaled 735,718 tons, a decline of 19 percent from 1948; electric power utilities consumed 3,353,857 tons, a decline of 15 percent; anthracite used in the manufacture of fuel briquets and packaged fuel totaled 646,897 tons in 1949, a decrease of 44 percent from 1948. Anthracite mixed with bituminous coal in making coke totaled 172,825 tons in 1949 compared with 256,175 tons in 1948.

Competitive Fuels in the United States and Principal Markets.—The New England and Middle Atlantic States, Maryland, Delaware, and the District of Columbia received 96 percent of the total shipments of anthracite to points in the United States in 1949. Data on the

consumption of all fuels in this market are not available; however, apparent consumption of anthracite, domestic coke, briquets, and heating and range oils, in terms of anthracite, totaled 80,939,000 net tons in 1949, a decrease of 16 percent from 1948. Fuel oil surpassed anthracite consumption in this area for the first time in 1947 on an equivalent B. t. u. or heating value basis, and, in 1949, accounted for 58 percent of the total consumption of the fuels indicated in table 26.

Supplies of various fuels generally used for space-heating purposes in the United States in 1949 decreased greatly from 1948. (*See* table 27.)

TABLE 26.—Apparent consumption of anthracite and selected competitive fuels in the principal anthracite markets, 1946–49

OIL (BARRELS OF 42 GALLONS)					
Oil sales for heating buildings:					
Range oil	32,259,000	60,564,000	74,114,000	84,163,000	[8] 78,529,000
Heating oils (domestic and commercial) [9]	116,617,000	189,371,000	234,761,000	258,663,000	[8] 254,902,000
Liquefied petroleum gases (domestic)	972,000	18,059,000	27,394,000	35,078,000	38,751,000
GAS (MILLION CUBIC FEET)					
Natural-gas consumption for domestic and commercial use [10]	489,234	902,622	1,087,363	1,219,402	[8] 1,366,000
Manufactured-gas sales for: [11]					
Residential use	210,959	272,797	291,274	295,797	(12)
Commercial use	42,631	62,571	68,566	71,558	(12)

[1] A considerable part of the smaller steam sizes is used by industries, railroads, and public utilities.
[2] U. S. Department of Commerce.
[3] Production plus imports less exports.
[4] Partly estimated.
[5] Data not available.
[6] An estimated one-half of total production shown is used for domestic purposes.
[7] Exact data not available.
[8] Estimated.
[9] Includes all grades of fuel oil used for heating buildings.
[10] Includes gas used for heating offices, hotels, apartments, hospitals, stores, and other large buildings, as well as houses.
[11] American Gas Association.
[12] Data not yet available.

Mechanical Stokers.—Data of the Bureau of the Census, United States Department of Commerce, show that factory sales of class 1 mechanical stokers for burning anthracite (capacity under 61 pounds of coal per hour) decreased from 9,524 units in 1948 to 4,604 units in 1949; sales of class 2 stokers (capacity 61 to 100 pounds of coal per hour) decreased from 761 units in 1948 to 478 units in 1949. Automatic anthracite-burning equipment has been improved greatly in recent years and the anthracite industry expects equipment sales to increase substantially in the next several years.

STOCKS

Stocks of anthracite held in producers' yards totaled 927,859 tons in January 1949, declined to a low of 442,117 tons in March, and then increased to 975,457 tons in December; virtually all of the coal in storage during the year was Pea and smaller sizes. Stocks of anthracite on the upper Lake docks totaled 246,825 tons in December 1949, a 35-percent decrease from those held in December 1948. Stocks held by electric power utilities increased 72 percent over 1948, while stocks of class 1 railroads declined 31 percent.

PRICES

According to Saward's Journal, f. o. b. mine prices for anthracite at the end of 1949 varied from $12.15 to $12.55 per net ton on Broken and Egg sizes; $12.25 to $12.55 on Stove and Chestnut; $10.25 to $10.60 on Pea; $7.00 to $7.25 on Buckwheat No. 1; $6.00 to $6.25 on Rice; and $4.60 on Barley. A number of companies normally sell coal of a certain grade from some mines at a small premium over the quoted circular prices. It is to be noted that the prices are f. o. b. mine quotations and differ from retail prices, which include transportation and dealer costs. Data compiled from reports of the Bureau of Labor Statistics, United States Department of Labor, showing retail prices, for certain fuels in selected cities, by months for 1949, are shown in table 28.

943785—51- -25

EMPLOYMENT

The Pennsylvania anthracite industry employed an average of 75,377 men in 1949, only 838 fewer than in 1948. The men worked an average of 195 days; and the average annual output per man was 560 net tons, a decrease over the annual per man output of 745 tons in 1948. Of the total employees, 53 percent were employed in operations in the Wyoming region, 17 percent in the Lehigh, and 30 percent in the Schuylkill region.

Employment data, as shown in this study, do not include workers employed in "bootleg" coal-mining operations, conducted principally in the Schuylkill region. According to the Anthracite Committee, 2,928 men were working 868 "bootleg" holes in February 1950. Although these workers are not included in the employment data, the coal produced by some (442,541 net tons in 1949) was purchased by the recognized industry for preparation and shipment to market, and the coal so purchased is included in the production tables of this chapter. Complete employment data on the "bootleg" holes from which this coal was produced are not available. Therefore, the

[1] Men employed in "bootleg" operations excluded.
[2] Output per man per day calculated on legitimate tonnages only; "bootleg" purchases excluded.
[3] Represents washeries for which both production and employment were separately reported.

purchased coal was deducted from the total tonnage reported by the operators, and the resulting net production was then used to calculate the output per man per day. Although it is true that men employed at preparation plants of the recognized companies were engaged part time in preparing this purchased coal for market, the omission of such time will not detract materially from the validity of the per ton figure obtained. See tables 29 and 30 for details on labor statistics.

[3] None in Wayne in 1949.

MINING METHODS AND EQUIPMENT

Mechanical Loading.—Mechanically loaded coal comprised 44 percent of the total underground production in 1949 compared with 42 percent in 1948; the quantity of anthracite loaded mechanically underground totaled 11,858,088 tons, a decline of 25 percent from 1948. The relatively flat coal seams of the Northern field are more adaptable to present-day mechanical loading methods than the sharply pitching seams in the other three fields; for this reason, 85 percent of the total tonnage mechanically loaded underground was produced in the former field and only 15 percent in the other fields. The trend in underground mechanical loading, hand loading, and stripping of Pennsylvania anthracite, 1928–49, is shown graphically in figure 2.

[1] As reported by Commonwealth of Pennsylvania, Department of Mines.

Strip-Pit Operations.—Anthracite recovered by strip-pit mining comprised 28 percent of the total fresh-mined production in 1949 compared with 27 percent in 1948; of the total 1949 strip-pit output (10,376,808 tons), 55 percent was produced in the Schuylkill region, 23 percent in the Lehigh region, and 22 percent in the Wyoming region. The high proportionate tonnage obtained by stripping in the Schuylkill and Lehigh regions is due largely to the relative ease of mining thick bed outcrops, whereas the beds in the Wyoming region are thinner, limiting the quantity of coal recoverable by strip-pit operations. Data on strip-pit mining are given in tables 34 and 35. Figure 3 shows graphically the production of anthracite from strip pits by regions, 1928–49.

TABLE 34.—Relative growth of Pennsylvania anthracite mined from strip pits, 1915, 1920, 1925, 1930, and 1944–49

Total	284	325	609	304	310	614	309	318	627

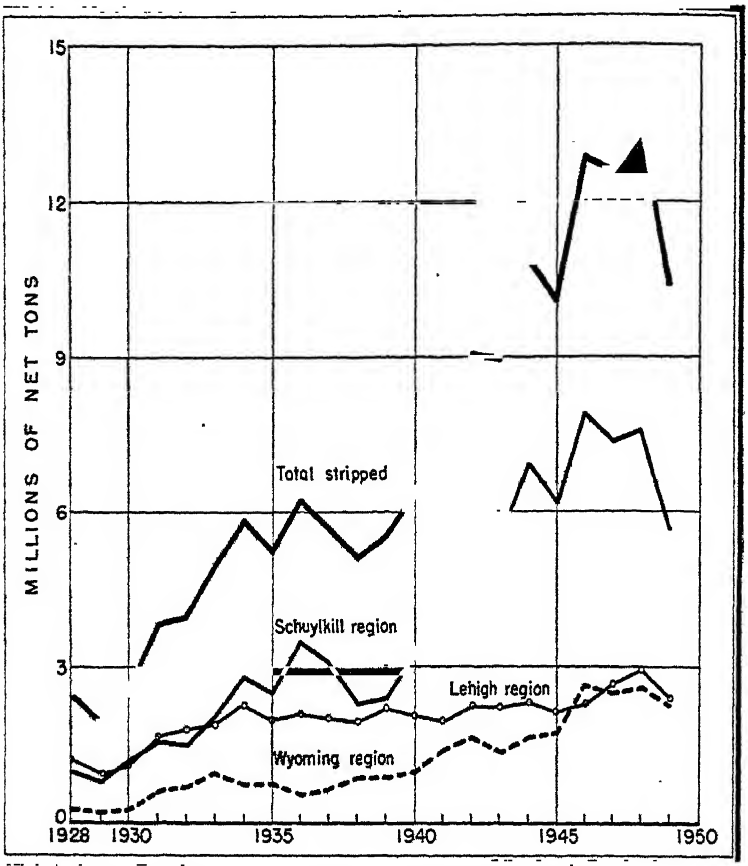

FIGURE 3.—Pennsylvania anthracite mined from strip pits, by regions, 1928–49.

Cutting Machines.—The quantity of anthracite cut by machines declined sharply in 1949 to 557,599 tons compared with 1,016,757 tons in 1948. The number of cutting machines in use in 1949 were 141 "permissible" and 12 "all other types," compared with 177 "permissible" and 28 "all other types" in 1948.

Dredge Coal.—The total quantity of anthracite recovered from the rivers and creeks draining the Pennsylvania anthracite fields declined to 865,122 tons in 1949, a decrease of 12 percent from 1948; virtually all of the coal recovered from the streams is Buckwheat No. 3 and smaller sizes used principally by electric power utilities and for other industrial purposes at points relatively near the streams from which the coal is recovered. Historical data on river-coal production are shown in table 36.

FOREIGN TRADE [4]

The decrease in shipments of Pennsylvania anthracite to Canada and European countries was largely responsible for the decline in exports from 6,675,914 tons in 1948 to 4,942,670 tons in 1949. The recession in shipments to Europe can be attributed largely to increased production of coal in Great Britain and other European countries, which enabled those countries to supply themselves with sufficient quantities of coal. The decrease in exports to Canada was caused largely by the abnormally warm weather in that country during the winter of 1949. There were no imports of anthracite into the United States in 1949.

CANADA

The production of coal in Canada continued to rise and in 1949 totaled 19,089,235 net tons, an increase of 20 and 3 percent, respectively, over 1947 and 1948. All of the Provinces except Nova Scotia showed substantial increases in 1949 over 1948; Nova Scotia reported a decline of 4 percent. Details on coal and coke statistics for Canada are shown in tables 40 and 41.

WORLD PRODUCTION

World production of anthracite declined slightly in 1949 from 1948. The decreased production of the United States was largely responsible for the decline in world output, inasmuch as a number of countries increased production substantially. Available data on world production by countries, for 1944–49 are given in table 42.

TABLE 42.—World production of anthracite in metric tons, 1944–49 [1]

[4] Estimate.
[5] Quality in doubt; may be bituminous.

Cobalt

By Hubert W. Davis

GENERAL SUMMARY

CONSUMPTION of cobalt in the United States continued at a high level in 1949 but was 6 percent less than the record established in 1948, when it exceeded 5,000,000 pounds for the first time. Usage of cobalt for cobalt-base high-temperature alloys and cemented carbides was greater in 1949 than in 1948, but these gains were more than offset by smaller use of cobalt in magnet alloys, high-speed and other steels, alloy hard-facing rods and materials, ground-coat frit for porcelain enamel, and pigments. Despite the high rate of use of cobalt in 1949, supplies substantially exceeded industry requirements, chiefly because of the record output of 4,350 metric tons from Belgian Congo ores.

Sales of cobalt metal in the United States were 12 percent smaller in 1949 than in 1948; sales to industry were 11 percent less and those to the National Stock Pile 13 percent smaller. The metal was supplied chiefly by imports but partly by production in the United States. Imports of metal in 1949 increased 6 percent over 1948, and domestic production of metal gained 2 percent. Suppliers' stocks of metal in the United States increased 19 percent.

The demand for cobalt oxide declined substantially in 1949, chiefly because of smaller use in ground-coat frit for porcelain enamel and in pigments; as a consequence, output of oxide in the United States and imports dropped 20 and 55 percent, respectively.

Production and shipments of cobalt hydrate and salts were larger in 1949 than in 1948, but those of driers were smaller.

The bulk of the cobalt metal, oxide, hydrate, and other cobalt products sold in the United States is made from crude cobalt (alloy) produced in Belgian Congo. Imports of alloy from Belgian Congo were 24 percent less in 1949 than in 1948. Some of the cobalt products sold are made from domestic and Canadian ores. Output of domestic ore was 24 percent smaller than in 1948, and imports of Canadian ore by refiners were down 91 percent. Consumption of cobalt alloy and ore was 4 percent smaller.

Effective April 1, 1949, the price of cobalt in metal and oxide was advanced 15 cents a pound.

The Reduction & Refining Co., Kenilworth, N. J., began refining Government-held ore and subgrade metal late in 1949.

The extraction of cobalt and its uses were described.[1]

DOMESTIC PRODUCTION

Mine Production.—Despite the fact that the United States is the largest consumer of cobalt in the world, only a small part of its requirements has been furnished by domestic ore, as is evident from the next table, which shows production and shipments through 1949.

Cobalt ore produced and shipped in the United States through 1949

Year	Produced		Shipped from mines

1949	19,599	521,656	25,175	673,773
Total	(1)	7,158,365	(1)	7,085,396

[1] Data not available.

Production of cobalt ore in the United States in 1949 was 24 percent less than in 1948, but shipments were 16 percent more.

The Bethlehem Steel Co. was the only producer of commercial cobalt ore in the United States in 1949. The cobalt-bearing material (averaging 1.3 percent cobalt in 1949) is contained in the sulfides that accompany the magnetite mined at Cornwall, Pa. The cobalt-bearing material is shipped to the Pyrites Co., Wilmington, Del., where it is processed to metal and other cobalt products.

The Sullivan Mining Co., Kellogg, Idaho, continued to recover cobalt at its electrolytic zinc plant in 1949 but, as in previous years, made no shipments. In 1949 it recovered 126 short tons of residues containing 10,338 pounds of cobalt.

Underground development was continued in 1949 at the Blackbird mine near Forney, Idaho, by the Calera Mining Co., a wholly owned subsidiary of the Howe Sound Co. Underground development consisted of preproduction drifting and raising. Surface construction comprised dormitories and houses at the townsite and erection of several buildings at the industrial site. A complete water and sewage system was installed. Some excavation work was done for the

mill. The ore carries copper and gold, as well as cobalt. According to the Howe Sound Co.:[2]

Research work in connection with milling the complex cobalt ore, and refining the cobalt product, continued. Work on the refining process, which has been under study for some time, was concluded. Additional research has, however, been started on an entirely new process which, if adaptable, may be more economical than the one which has been completely developed. Within six months it is anticipated that full information in regard to the applicability of this alternate process will be available.

Refinery Production.—Consumption by refiners or processors of cobalt contained in alloy and ore was 2,607,281 pounds in 1949, a decrease of 4 percent from 1948. However, usage of cobalt intermediates by refiners or processors was 2 percent greater. Of the alloy and ore consumed in 1949, much the greater part was utilized in making cobalt metal. The remainder of the alloy and ore and all of the other cobalt raw materials were used in manufacturing the cobalt products shown in the accompanying table.

Cobalt consumed[1] by refiners or processors in the United States, 1945–49, in pounds of contained cobalt

Cobalt material	1945	1946	1947	1948	1949
Alloy and ore	4,808,825	2,009,018	2,672,991	2,715,605	2,607,281
Fines and granules	453,538	499,737	528,544	393,726	422,493
Rondelles	64,872	148,197	128,937	107,520	95,759
Hydrate	133,831	128,740	152,102	150,826	129,444
Carbonate	18,460	19,243	6,904	4,606	2,664
Other	----------	----------	----------	----------	17,565

[1] The fines, granules, rondelles, hydrate, and carbonate consumed originated from alloy and ore; therefore, combining alloy and ore with these materials would result in duplication.

Specified cobalt products[1] produced and shipped in the United States, 1948–49, in pounds

Driers	8,301,277	490,360	8,234,863	491,395

[1] In addition, cobalt metal (rondelles, granules, fines, and powder) was produced, but the Bureau of Mines is not at liberty to publish figures on production and shipments.

[2] Howe Sound Co., Annual Report: 1949, p. 5.

CONSUMPTION

Consumption of cobalt by industrial consumers continued at a high rate in 1949 but was 6 percent under the record established in 1948; it was 4,701,926 pounds in 1949. Magnet alloys continued to be the largest single use for cobalt and accounted for 26 percent of the total quantity consumed in 1949; usage for this purpose, however, was 8 percent less than in 1948. The development of two permanent magnet materials—Alnico 7 and Alnico 5 DG—was announced in 1949. Alnico 7 was designed primarily for all applications where a high demagnetization force is present, particularly in motors, generators, and air-gap devices. Alnico 5 DG, which was in the sampling stage, was developed for improved quality at an increased price for general use. Typical applications for Alnico 5 DG are loudspeakers and magnetic assemblies which require a high field strength and which are magnetized after final assembly, such as holding magnet assemblies, magnetic chucks, and radar assemblies. The more recent applications for Alnico magnets are primarily centered around the television industry. However, the communication, magnetic separator, and novelty fields of application continue to use much the greater share of magnets produced. A permanent Alnico magnet designed to serve as a clamp for the ground cable on electric welders is now being marketed.[3] The casting of alloys for permanent magnets has been discussed.[4]

The second-largest use for cobalt was for cast cobalt-chromium-tungsten-molybdenum alloys, which accounted for 20 percent of the total quantity consumed in 1949; moreover, usage for this purpose was 12 percent greater than in 1948. An alloy suitable for use at high temperatures, which contains 5 to 7 percent cobalt, is the subject of

Cobalt consumed in the United States, 1946–49, by uses, in pounds of cobalt

United States Patent 2,460,817. Cobalt-base alloys containing 80 percent cobalt are the subject of United States Patent 2,469,715.

A substantial gain in the use of cobalt in cemented carbides was recorded in 1949. A comprehensive article on cemented carbides was made availabe.[5]

Utilization of cobalt in ground-coat frit for porcelain enamel and in pigments reversed upward trends that have persisted since 1942; and less cobalt was also used in high-speed and other steels and in alloy hard-facing rods and materials.

An eight-metal alloy—Octanium—of which cobalt is a component, was developed for use in the nib (point) of fountain pens.

PRICES

Effective April 1, 1949, the price of cobalt metal (97–99 percent, in kegs of 550 pounds) was raised to $1.80 a pound delivered east of Chicago; and for quantities under 100 pounds it was increased to $1.87 a pound. Metallurgical-grade oxide was also raised to $1.80 a pound of contained cobalt, f. o. b. Niagara Falls, N. Y., and ceramic-grade oxide to $1.38 a pound (gross weight) east of the Mississippi River. The former prices, which had been in effect since July 1, 1947, were $1.65, $1.72, $1.65, and $1.27 a pound, respectively.

FOREIGN TRADE[6]

Imports.—Imports of cobalt into the United States in 1949 were 15 percent smaller than in 1948, which, however, was an all-time

Cobalt imported for consumption in the United States, 1945–49, by classes

[6] Figures on imports and exports (unless otherwise indicated) compiled by M. B. [illegible], of the Bureau of Mines, from records of the U. S. Department of Commerce.

record. Belgian Congo continued to be the chief source of imports; in 1949 it supplied 3,396,590 pounds of metal and 3,691,051 pounds of alloy containing 1,657,788 pounds of cobalt. Belgium supplied 2,180,650 pounds of metal and 360,150 pounds of oxide containing 255,160 pounds of cobalt; both the metal and oxide were produced from Belgian Congo alloy. Canada supplied 168 pounds (gross weight) of oxide and 106,690 pounds of ore containing 11,698 pounds of cobalt and Denmark 2,319 pounds of ore containing 267 pounds of cobalt. The United Kingdom supplied 64 pounds of metal and 359 pounds (gross weight) of salts and compounds. Finland supplied 11,023 pounds of metal. The imports from Finland were the first since 1940.

The accompanying historical table shows imports of cobalt for 1923–49, by classes. Corresponding figures for earlier years are not available. However, imports of cobalt apparently did not exceed 500,000 pounds annually until 1926; from that year they increased steadily through 1929, when they reached 1,212,000 pounds. Imports declined abruptly during 1930–32, dropping to 303,000 pounds in 1932. Since 1933, however, imports of cobalt have increased almost steadily and reached an all-time high of 8,821,000 pounds in 1948.

During the 27 years 1923–49, receipts of metal comprised about 43 percent of the cobalt imports, most of which was supplied by Belgium and Belgian Congo. Smaller quantities of metal have been received from Austria, Canada, Finland, France, Germany, Japan, Sweden,

Cobalt imported for consumption in the United States, 1923–49, in pounds

[1] In addition to classes shown, 4,796,000 pounds of Burmese speiss containing 335,721 pounds of cobalt were imported.

and United Kingdom. Imports of alloy represented the second-largest quantity (40 percent), and virtually all was from Belgian Congo. About 12 percent of the imports of cobalt have been in the form of oxide, chiefly from Belgium. Substantial quantities of oxide have also been received from Germany and Canada, and smaller quantities from Australia, Finland, and France. Receipts of cobalt ore have accounted for about 5 percent of the total imports; Canada has been the largest source and most of the remainder came from Australia and French Morocco.

Exports.—Exports of cobalt from the United States are small; 164,868 pounds of metal (including scrap) valued at $55,933 were exported in 1949. Some oxide, salts, and driers are also exported, but the figures are not separately recorded by the United States Department of Commerce.

Tariff.—The duty on cobalt oxide continued to be 10 cents a pound, sulfate 5 cents a pound, linoleate 10 cents, and other salts and compounds 30 percent ad valorem. Cobalt metal and ore entered the United States duty free.

WORLD REVIEW

Virtually all cobalt is found associated with other metals, such as copper, nickel, iron, arsenic, lead, zinc, manganese, silver, and gold. Belgian Congo and Northern Rhodesia, where cobalt occurs associated with copper, have been the chief producing countries in recent years, followed by the United States, Canada, and French Morocco. These five countries have contributed about 95 percent of the world output of cobalt in recent years. Iron pyrites from Finland, Germany, Greece, Italy, Norway, Spain, and Sweden contains cobalt, some of which is recovered. Although the quantities of cobalt present in iron pyrites are generally very small—often only 0.05 percent—and its

[1] In addition to countries listed, Brazil, China, Germany, and Spain produce cobalt, but production data are not available. Estimate by author of chapter included in total.
[2] Data not available; estimate by author of chapter included in total.
[3] Less than 1 ton.
[4] Figures comprise Canadian ore processed in Canada and exported (irrespective of year when mined), plus cobalt content of oxide made at Port Colborne from copper-nickel ore. However, figures exclude the cobalt recovered at Clydach (Wales) from Canadian nickel-copper ores, for which estimate by author of chapter has been included in world total.
[5] Year ended June 30 of year stated.

recovery is only 50 to 60 percent, the very large tonnage treated during and preceding the war contributed greatly to the cobalt production in Germany. It is reported[7] that about 10 tons of cobalt concentrates are obtained from 100,000 tons of cinder. A complete record of output of cobalt from iron pyrites is lacking.

Australia.—The only production of cobalt in Australia for many years has been obtained from the lead-zinc-silver ores of Broken Hill, New South Wales. The cobalt is recovered at Risdon, where it is converted into metal, oxide, and sulfate containing about 11 to 15 metric tons of cobalt annually.

Belgian Congo.—The world's premier source of cobalt continues to be Belgian Congo, where the Union Minière du Haut-Katanga is the sole producer. Output was 4,350 metric tons in 1949, a new record. Production of cobalt in Belgian Congo was begun in 1924, and since that year output has increased almost without interruption and total production through 1949 has been 36,706 metric tons.

Production of cobalt in Belgian Congo, 1924–49, in metric tons of contained cobalt

1936	685		
1937	1,500	Total	36,706

The Union Minière du Haut-Katanga has a cobalt mine and a cobalt-concentrating plant at Kabolela and a cobalt mine and ore-treatment plant at Kamoto. Its Ruashi mine near Elisabethville is planned to be reopened. At Jadotville the company has six single-phase electric furnaces (total monthly capacity, about 300 tons) for smelting cobalt-bearing ores and slags. The cobaltiferous red alloy from the electric furnaces is refined in two rotary furnaces; and the resultant crude cobalt, which is cast into ingots, is shipped chiefly to company refining plants at Niagara Falls, N. Y., and Oolen, Belgium, for processing the crude cobalt to metal, oxide, salts, and driers. The solutions used in the electrolytic copper plants contain cobalt, recovered by precipitation. The precipitates are treated by electrolysis in a refining plant (also at Jadotville) capable of producing about 225 tons a month of high-purity granules. The total refining capacity of the company plants at Niagara Falls, N. Y., Oolen, Belgium, and Jadotville, Belgian Congo, is about 7,500 tons annually. The program for expanding the capacity of the Kolwezi and Kipushi concentrators and the electrolytic plant (copper and cobalt) at Jadotville-Shituru continued in 1949. The first of the two new power stations at Centrale Bia was completed. On the basis of a rate of production of 4,000 metric tons annually, the company reported developed re-

[7] Dennis, W. H., Recovery of Nonferrous Metals from Pyrite: Mine and Quarry Eng. (London), vol. 13, No. 12, December 1947, pp. 358-362.

serves of cobalt adequate for 40 to 50 years, and it anticipates that these reserves will increase as a result of further development of its copper deposits.

Canada.—Production of cobalt in Canada is measured by the quantities of Canadian ores processed and exported, irrespective of the year when mined, plus the cobalt content of oxide made by the International Nickel Co. of Canada, Ltd., at Port Colborne, Ontario. Canadian production figures, however, do not include the cobalt recovered by the Mond Nickel Co. at its Clydach (Wales) nickel refinery from the nickel-copper ores of the Sudbury district.

According to the Dominion Bureau of Statistics, production of cobalt (content) in Canada was 613,600 pounds in 1949 compared with 1,544,852 pounds in 1948. The major portion of the output credited to Canada in 1948 came from accumulations during the war years rather than from ores mined in 1948. Cobalt ore was discovered in northern Ontario in 1903; production began in 1904. The name "Cobalt" was given to the district that for many years thereafter furnished the greater part of the world's supply. Recovery of cobalt from the copper-nickel ore of the Sudbury district was begun in 1947. Production of cobalt in Canada from 1904 through 1949 has been as follows.

Production of cobalt in Canada, 1904–49, in short tons of contained cobalt [1]

[1] Excludes cobalt recovered at Clydach (Wales) from Canadian copper-nickel ores.

The International Nickel Co. of Canada, Ltd., at its Canadian nickel refinery, continued the recovery of cobalt as oxide from the nickel-copper ores of the Sudbury district. Output of cobalt in oxide was reported as 15 short tons monthly in 1948. It was reported that recovery of cobalt would be greater in 1950.

Falconbridge Nickel Mines, Ltd., continued construction, at its nickel refinery at Kristiansand, Norway, of a plant to produce cobalt oxide and electrolytic cobalt, which will be made from the cobalt recovered from the matte produced from Sudbury nickel-copper ores.

In the cobalt area of northern Ontario, the Cobalt Chemical &

Refinery Co. (successor to Silanco Mining & Refining Co., Ltd.) was the chief producer. It operated the Colonial concentrator, which treated ore from the Beaver mine. The construction of a smelter, begun in 1945 by the Silanco Mining & Refining Co., Ltd., was completed in 1949. It is reported that the New Cross Chemical Co. plans to construct a plant adjacent to the smelter of Cobalt Chemical & Refinery Co. to produce salts, oxides, and other cobalt products.

French Morocco.—Production of cobalt ore in French Morocco was 1,739 metric tons containing 209 tons of cobalt in 1949 compared with 2,094 tons containing 278 tons of cobalt in 1948. La Société Minière de Bou-Azzer et du Graara, Casablanca, is the sole producer. The ore, which also contains nickel, gold, and silver, is shipped to Belgium for processing to oxide and speiss, which are exported to France, where the speiss is refined to metal.

Germany (Bizonia).—Production of cobalt derived from pyrites residues in Bizonia was 80 to 90 metric tons in 1948.[8]

Northern Rhodesia.—The second-largest producer of cobalt in the world continues to be Northern Rhodesia, where the Rhokana Corp., which has been producing cobalt since 1933, is the sole producer. The 4-year downward trend in production was reversed in 1949, when the output of alloy was 1,171 short tons containing 443 tons of cobalt in the year ended June 30, compared with 1,081 tons containing 405 tons in 1948. Laboratory and pilot-plant investigations on the production of electrolytic cobalt from a flotation concentrate recovered by the Rhokana Corp. have been described.[9] As a consequence of new methods for recovering cobalt from copper ores which have low cobalt content and of the authorization of $550,000 by the Economic Cooperation Administration to finance American equipment for expanding the plant of the Rhokana Corp., it is expected that Northern Rhodesian production of cobalt will increase substantially by 1951.

Coke and Coal Chemicals

By J. A. DeCarlo, J. A. Corgan, and Maxine M. Otero

GENERAL SUMMARY

PRODUCTION of oven and beehive coke in the United States in 1949 totaled 63,637,429 net tons, a decline of 15 percent from the record output of 1948. The decline was due largely to (1) complete work stoppages for various periods in both the steel and bituminous-coal industries beginning in September, (2) initiation of a 3-day workweek at bituminous-coal mines in July, and (3) slackening in steel demand in the second quarter of the year. Oven-coke production started to decline slightly during the latter half of March and in October fell to the lowest figure since May 1946 because the steel strike, beginning at midnight September 31, forced virtually all "furnace" oven-coke plants to bank their ovens until a new management-labor contract was negotiated about the middle of November. Although production increased rapidly thereafter, output for the year dropped 12 percent from 1948. Beehive-coke operations were affected to an even greater extent, as the 3-day workweek, beginning in July, caused virtually all of the active plants to suspend operation for the rest of the year, and production dropped 48 percent.

A significant development in 1949 was the substantial increase in the proportion of washed coal charged into ovens. The necessity of using more low-grade coals for the manufacture of metallurgical coke has made it imperative to clean the inferior coals. Thus, in 1949, more than 38 percent of the bituminous coal carbonized in slot-type ovens and 20 percent of the coal for beehive ovens was washed, compared with 29 and 18 percent, respectively, in 1948. The influence of washing coal on coke properties and on gas and coal-chemical materials yield was reflected in the improvement in fuel efficiency of blast furnaces and the increase in yields of gas, tar, crude light oil, and ammonia. The yield of coke per ton of coal charged, however, declined slightly from the 1948 figure.

Cost of coal, the principal item of expense in the manufacture of coke and naturally influencing coke prices, continued to advance in 1949 because of increases in mining, preparation, and transportation costs. The average cost of coal delivered to oven-coke plants rose $0.39 per ton or 5 percent to $8.52, a new peak. Coal costs for beehive ovens also soared to a new level, rising $0.31 per ton or 6 percent over the 1948 figure. These increases resulted in higher prices on coke, and average receipts per ton of oven coke sold (merchant sales) advanced 2 percent for blast-furnace coke, 5 percent for foundry, 3 percent for water gas, 1 percent for other industrial, and 3 percent for domestic. For beehive coke, gains were registered for all grades except that sold for residential heating, which dropped 8 cents per ton or about 1 percent from 1948. The average value per ton of beehive coke sold for use in

blast furnaces and in the manufacture of water gas showed the sharpest gains, with increases of 7 percent each.

The effect of operating oven-coke plants near capacity levels since the beginning of World War II became apparent in 1949, and a large number of inefficient and deteriorated ovens had to be replaced. In all, 469 new slot-type ovens with an annual coke capacity of more than 2¼ million tons were completed and placed in operation during the year. In spite of this record, it is to be noted that the total number of ovens and annual coke capacity of the oven-coke industry dropped below the figures reported at the end of 1948. This is evidence that new construction in 1949 did not pace obsolescence, and construction of new ovens undoubtedly will have to be continued at a rapid pace in the future if oven-coke capacity is to be maintained at current or slightly higher levels. That oven-coke plant operators recognize this problem is shown by the large number of new ovens under construction at the close of the year.

Demands for coke for metallurgical and industrial purposes continued at extremely high levels throughout the year, and there was little change in the use pattern from preceding years. About 81 percent of the oven coke produced was utilized by blast furnaces, 4 percent by iron foundries, 7 percent for the manufacture of producer gas and water gas, 3 percent for miscellaneous industrial uses, and only 5 percent for residential heating. Beehive ovens shipped 84 percent of their production to blast furnaces, 6 percent to foundries, 3 percent for water-gas manufacture, 6 percent for other industrial purposes, and less than 1 percent for residential heating. The market for coke for household or residential heating has been shrinking steadily in the past decade, largely because of competition from oil and gas and also because of the increased requirements for metallurgical purposes.

Preliminary data from the Bureau's 1949 annual survey show that 21,200 men were employed at oven-coke plants and worked 58,930,000 man-hours—decreases from 1948 of 677 men and 4,858,377 man-hours. The number of men employed at beehive plants increased from 3,280 in 1948 to 3,400 in 1949, but the man-hours worked dropped from 6,233,002 to 3,550,000. The reduction in man-hours worked was due to the closing of virtually all beehive plants, beginning in July, while the increase in men was attributable to the large number of operations that were active, particularly during the first quarter of the year.

Production of the principal coal-chemical materials—gas, tar, ammonia, and crude light oil—which invariably accompany the production of oven coke all showed decreases when compared with 1948 figures. Coke-oven gas production declined 11 percent; tar, 9 percent; ammonia, 9 percent; and crude light oil, 11 percent. It is to be noted, however, that although the total production of these materials decreased, the average yield per ton of coal carbonized increased slightly, indicating an improvement in coal quality. Prices of the various coal chemicals varied only slightly from those of 1948. The total value of coke and breeze produced and coal-chemical materials sold exceeded a billion dollars for the third consecutive year.

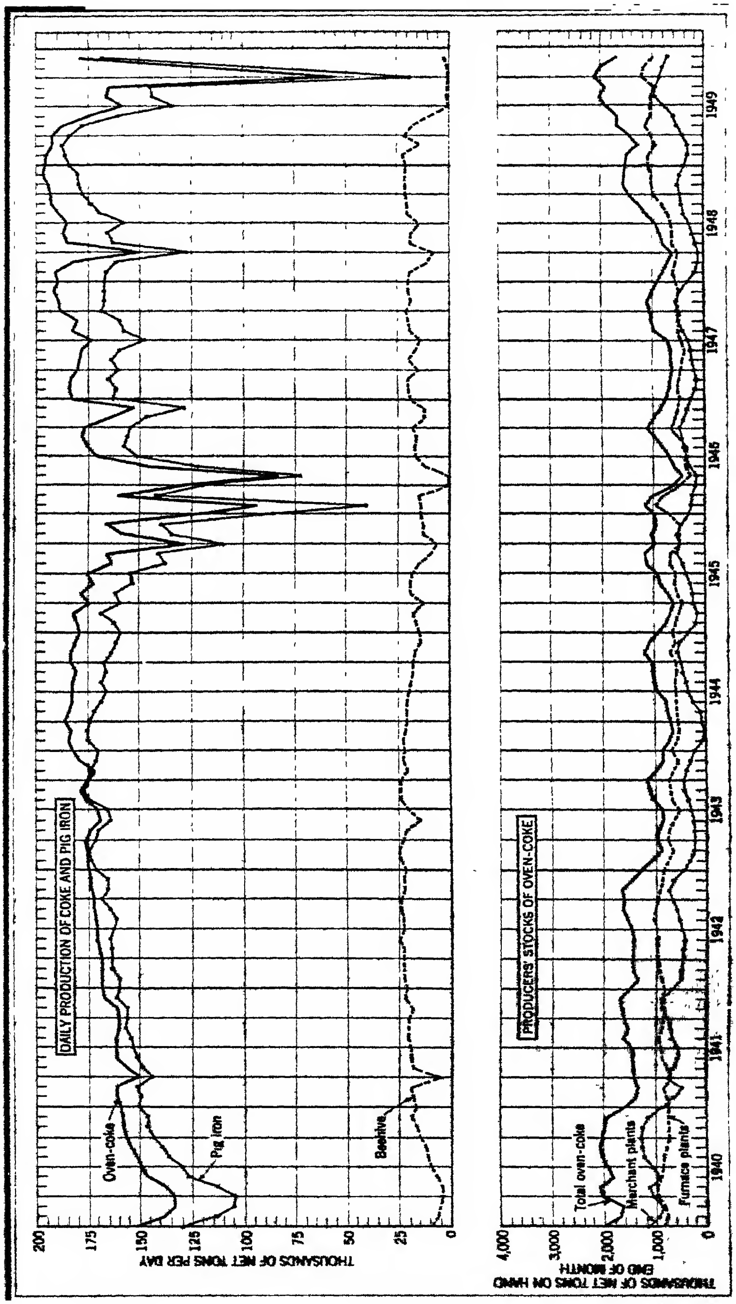

FIGURE 1.—Average daily production of oven and beehive coke and pig iron and producers' stocks of oven coke, 1940–49, by months.

TABLE 1.—Salient statistics of the coke industry in the United States in 1949

	Slot-type ovens	Beehive ovens	Total
Coke produced—			
At merchant plants:			
Net tons	12,112,922	(1)	(1)
Value	$181,084,964		
At furnace plants:			
Net tons	48,109,559		
Value	$617,707,105		
Total:			
Net tons	60,222,481	3,414,948	63,637,429
Value	$798,792,069	$43,945,627	$842,737,696
Screenings or breeze produced:			
Net tons	4,929,086	59,494	4,988,580
Value	$16,935,002	$129,436	$17,064,438
Coal charged into ovens:			
Bituminous:			
Net tons	85,881,576	5,354,495	91,236,071
Value	$732,076,635	$29,043,896	$761,120,531
Average per ton	$8.52	$5.42	$8.34
Anthracite:			
Net tons	172,825		172,825
Value	$1,269,973		$1,269,973
Average per ton	$7.35		$7.35
Total:			
Net tons	86,054,401	5,354,495	91,408,896
Value	$733,346,608	$29,043,896	$762,390,504
Average per ton	$8.52	$5.42	$8.34
Average yield in percent of total coal charged:			
Coke	69.98	63.78	69.62
Breeze (at plants actually recovering)	5.76	3.53	5.72
Ovens:			
In existence Jan. 1	15,139	14,078	29,217
In existence Dec. 31	15,104	13,662	28,766
Dismantled during year	504	647	1,151
In course of construction Dec. 31	562		562
Annual coke capacity Dec. 31 net tons	73,710,100	8,672,200	82,382,300
Coke used by producer—			
In blast furnaces:			
Net tons	35,046,393	67,518	35,113,911
Value	$451,981,030	$1,137,134	$453,118,164
In foundries:			
Net tons	80,395		80,395
Value	$1,230,026		$1,230,026
To make producer gas:			
Net tons	790,910		790,910
Value	$9,538,902		$9,538,902
To make water gas:			
Net tons	1,313,785		1,313,785
Value	$16,167,896		$16,167,896
For other purposes:			
Net tons	356,298	1,779	358,077
Value	$3,874,475	$25,102	$3,899,577
Coke sold—			
To financially affiliated companies—			
For blast-furnace use:			
Net tons	10,656,809	1,094,907	11,751,716
Value	$135,672,369	$12,324,470	$147,996,839
For foundry use:			
Net tons	52,433		52,433
Value	$1,158,472		$1,158,472
For manufacture of water gas:			
Net tons	721,076		721,076
Value	$9,867,867		$9,867,867
For other purposes:			
Net tons	192,713	554	193,267
Value	$2,573,912	$8,045	$2,581,957
To other consumers—			
For blast-furnace use:			
Net tons	2,950,619	1,698,607	4,649,226
Value	$41,574,447	$22,580,450	$64,154,897
For foundry use:			
Net tons	2,446,160	199,880	2,646,040
Value	$48,241,594	$3,050,392	$51,291,986
For manufacture of water gas:			
Net tons	1,267,885	114,973	1,382,858
Value	$17,135,440	$1,609,793	$18,745,233

See footnote at end of table.

TABLE 1.—Salient statistics of the coke industry in the United States in 1949—Continued

	Slot-type ovens	Beehive ovens	Total
Coke sold—Continued			
To other consumers—Continued			
For other industrial use:			
Net tons	1,452,791	199,908	1,652,699
Value	$20,258,191	$2,706,581	$22,964,772
For domestic use:			
Net tons	2,740,987	14,853	2,755,840
Value	$37,014,772	$175,269	$37,190,041
Disposal of screenings or breeze:			
Used by producer—			
For steam raising:			
Net tons	3,199,101	1,141	3,200,242
Value	$10,550,793	$4,704	$10,555,497
To make producer or water gas:			
Net tons	116,436		116,436
Value	$615,816		$615,816
For other purposes:			
Net tons	722,308	9	722,317
Value	$2,298,843	$115	$2,298,958
Sold:			
Net tons	1,055,459	35,531	1,090,990
Value	$4,106,014	$68,452	$4,174,466
Average receipts per ton sold (merchant sales):			
Furnace coke	$14.09	$13.29	$13.80
Foundry coke	$19.72	$15.26	$19.38
Water-gas coke	$13.51	$14.00	$13.56
Other industrial coke	$13.94	$13.54	$13.90
Domestic coke	$13.50	$11.80	$13.49
Screenings or breeze	$3.89	$1.93	$3.83
Stocks on January 1, 1950:			
Furnace coke ... net tons	838,718	51,580	890,298
Foundry coke ... do	13,120	1,118	14,238
Domestic and other coke ... do	864,720	200	864,920
Screenings or breeze ... do	1,433,289	7,327	1,440,616

SCOPE OF REPORT

The statistics in this chapter, except where otherwise noted, are based on data voluntarily supplied to the Bureau of Mines by coke-plant operators in the United States. The characteristic form and manner of presentation of material developed in preceding chapters is adhered to in this report, carrying the Bureau's series on coke and coal-chemical materials through 1949. In accordance with this procedure, most of the statistical tables herein include comparable data for three or four preceding years. The statistics are confined to the operation of high-temperature beehive and slot-type coke-oven plants. Salient statistics on medium- and low-temperature carbonization are shown separately in table 4 and similar data on the operation of coal-gas retorts are given in table 5. Coke is made by other processes not included in this report, namely, from the refining of petroleum and crude tar. Preliminary data for 1949 indicate that the production of petroleum coke totaled 3,392,000 net tons and output of pitch coke, as reported by the United States Tariff Commission, totaled 43,000 net tons. The standard unit of measurement in the coke industry in the United States is the short or net ton of 2,000 pounds. Unless otherwise specified, it is the unit employed throughout this chapter.

MEDIUM- AND LOW-TEMPERATURE COKE

TABLE 4.—Salient statistics of medium- and low-temperature carbonization plants in the United States in 1949

	Quantity	Value
Coke produced ... net tons	124,459	$1,153,082
Coal carbonized ... do	208,127	675,280
Average per ton		3.24
Average yield of coke in percent of coal carbonized	59.80	
Ovens and retorts:		
In existence Dec. 31	26	
Annual coke capacity Dec. 31 ... net tons	368,200	
Tar produced ... gallons	2,309,660	
Yield per ton of coal ... do	11.10	
Value of coke and breeze produced and coal-chemical materials sold		1,509,741

RETORT COKE

TABLE 5.—Salient statistics of the coal-gas industry in the United States in 1949 [1]

	Horizontal retorts	Vertical retorts	Total
Coke produced:			
Net tons	111,230	268,191	379,421
Value	$1,409,470	$2,982,837	$4,392,307
Screenings or breeze produced ... net tons	15,228	43,168	58,396
Coal charged into retorts:			
Net tons	172,224	450,986	623,210
Value	$1,933,764	$4,884,292	$6,818,056
Average per ton	$11.23	$10.83	$10.94
Average yield in percent of coal charged:			
Coke	64.58	59.47	60.88
Breeze (at plants actually recovering)	9.36	10.39	10.10
Retorts:			
In existence Dec. 31	586	272	858
In operation Dec. 31	329	208	537
Annual coal capacity ... net tons	246,000	537,700	783,700
Coke used by producers:			
Net tons	62,863	159,508	222,371
Value	$763,686	$1,661,066	$2,424,752
Coke sold to other consumers:			
Net tons	41,887	98,349	140,236
Value	$551,665	$1,178,760	$1,730,425
Stocks on Jan. 1, 1950:			
Coke ... net tons	10,221	47,609	57,830
Breeze ... do	3,183	1,439	4,622
Coal-chemical materials:			
Tar:			
Production ... gallons	2,146,775	6,599,539	8,746,314
Sales ... do	2,246,396	7,340,742	9,587,138
Value of sales	$154,402	$559,602	$714,004
Stocks on Jan. 1, 1950 ... gallons	355,926	918,363	1,274,289
Per ton of coal charged ... do	12.47	14.63	14.03
Crude light oil: [2]			
Production ... do	22,747	196,161	218,908
Sales ... do	27,109	204,920	232,029
Value of sales	$2,169	$16,311	$18,480
Stocks on Jan. 1, 1950 ... gallons	7,200	28,727	35,927
Per ton of coal charged ... do	0.89	1.43	1.35

[1] Additional data in Bureau of Mines, Production of Coke and Coal Chemicals from Coal-Gas Retorts in 1949: Mineral Market Rept. 1839, Mar. 23, 1950.
[2] Includes drip oil.

OVEN AND BEEHIVE COKE AND COKE BREEZE

GROWTH OF INDUSTRY

TABLE 6.—Historical statistics of the coke industry in the United States, 1880 and 1890–1949

Year	Production (million net tons): Oven coke	Production (million net tons): Beehive coke	Production (million net tons): Total	Percent of total production from slot-type ovens	Ovens in existence: Slot type	Ovens in existence: Beehive	Slot-type ovens under construction at end of year	Coal charged (million net tons)	Yield of coke from coal (percent)	Average value of coke per ton at plant	Total value at plant (million dollars): Beehive coke	Total value at plant (million dollars): Oven coke	Total value at plant (million dollars): All coal-chemical materials [1]	Total value at plant (million dollars): Total coke and coal-chemical materials
1880	------	3.3	3.3	------	------	12,372	------	5.2	63.7	$1.99	7	------	------	7

[1] Value for tar up to and including 1917 represented that of tar "obtained and sold" which did not always include value of tar used by producer. Beginning with 1918, tar used by producer is specifically included. Value of breeze produced at oven-coke plants is included for those years for which it was reported, namely, 1916, 1917, and 1919–49. For other coal-chemical materials, only value of those sold is included. Value of breeze produced at beehive plants is not included, as it has usually been much less than a million dollars.

[2] [illegible] value of the coal-chemical materials available.

MONTHLY AND WEEKLY PRODUCTION

Statistics on monthly production of coke shown in tables 7 to 9 are based upon reports received from producers. Weekly production of beehive coke shown in table 10 is estimated from reports of carloadings received from all coke-carrying railroads. The totals shown in these tables have been adjusted to the total ascertained by an annual canvass of the producers. Data on weekly production of beehive coke are published by the Bureau of Mines in the Weekly Anthracite and Beehive-Coke Report and monthly data for both oven and beehive coke are summarized in the Monthly Coke Report. These publications are distributed, free of charge, upon request to the Publications Distribution Section, Bureau of Mines, Washington 25, D. C.

TABLE 7.—Coke produced in the United States, 1937 and 1947–49, by months and average per day, in net tons [1]

[1] Before 1942 daily average production of beehive coke was calculated by subtracting Sundays and holidays in each month; 1942–49 daily average has been calculated by dividing total monthly production by total number of days in month.

TABLE 8.—Oven coke produced in the United States in 1949, by States and months, in net tons

PRODUCTION BY FURNACE AND MERCHANT PLANTS

Tables 11 and 12 show the production of oven coke by plants associated with iron blast furnaces designated by the Bureau of Mines as "furnace" plants and by other plants classified as "merchant." This classification applies only to oven-coke plants and is maintained by the Bureau of Mines in the interest of those who wish to follow the coking activities of the two groups. There were no changes in 1949 in the number of furnace and merchant plants that produced coke. The close relationship between the furnace-coke plants and the iron and steel industry is clearly illustrated in the production trend in 1949. The furnace oven-coke plants and blast furnaces, which in January operated at about 95 and 96 percent of capacity, respectively, started to cut back production in the second quarter because of a slackening in steel demand and dropped to a low of 18 and 10 percent in October because of the strike in the iron and steel industry. Coke production increased rapidly upon settlement of the strike in November, and by December, the furnace plants were operating at a slightly higher rate than the merchant group. The latter group, because of its diversified interests, did not make such drastic changes in their oven operations. Although production in 1949 fluctuated more than in 1948, the rate of operation varied from a high of 95 percent in the months of January

and February to a low of 66 in October. In spite of the more uniform operating rate of the merchant plants, this group accounted for only 20 percent of the total output of oven coke in 1949, reflecting the influence of the steel industry on coke production.

TABLE 11.—Number and production of oven-coke plants connected with iron furnaces and of other plants in the United States, 1913, 1918, 1937, and 1947–49

Year	Number of active plants		Coke produced (net tons)		Percent of production	
	Furnace plants	Merchant plants	Furnace plants	Merchant plants	Furnace plants	Merchant plants
1913	20	16	9,277,832	3,436,808	73.0	27.0
1918	36	24	19,220,342	6,777,238	73.9	26.1
1937	43	42	36,134,209	13,076,539	73.4	26.6
1947	54	32	52,860,850	13,807,609	79.2	20.8
1948	55	31	54,951,858	13,332,499	80.5	19.5
1949	55	31	48,109,550	12,112,922	79.9	20.1

PRODUCTION BY STATES AND DISTRICTS

There has been a marked change in the principal producing centers of coke in the last half century. In the early days of the coke industry, beehive-coke ovens were the principal source of metallurgical fuel, and the principal centers of coke production were naturally those States with ample supplies of coking coal. Thus, in 1910, Pennsyl-

vania accounted for 63 percent of the total output of coke in the United States, and West Virginia and Alabama for 9 and 8 percent, respectively. Development of the slot-type coke oven and its adaptation to the production of blast-furnace coke, with the added advantage of recovering the valuable chemical raw materials, resulted in a shifting of the centers of coke production from the coal fields to areas near the sources of iron-ore supply or near the steel-consuming centers. This development enabled Ohio, Indiana, New York, and Illinois to expand coke-making facilities and the quantity of coke produced in these States increased steadily. Other States located great distances from coal-producing fields constructed oven-coke plants in ensuing years; and in 1949, coke was produced in 22 States scattered from the Pacific Ocean to the Atlantic Seaboard and from the Canadian border to the Gulf of Mexico. Pennsylvania maintained its rank as the leading oven-coke producing State, supplying 25 percent of the total United States output. Ohio, which produced only modest quantities (less than a million tons and ranking ninth) until the beginning of World War I, added coke ovens at a tremendous rate and by the end of that war had gained second place, a position maintained since. The output of oven coke in Ohio in 1949 represented 15 percent of the total production. Indiana has been third since 1917, supplying 13 percent of the total in 1949, and Alabama and New York together accounted for 17 percent.

NUMBER AND TYPE OF OVENS

Slot-Type Coke Ovens.—In spite of the high level of construction maintained by coke-plant operators in 1949, the total number of ovens in existence at the close of the year was 35 less than at the close of 1948. This development clearly shows that virtually all of the new ovens completed were replacements of old batteries. The estimated life of the batteries depends on the operating conditions at each plant and upon the decision of the owners as to when maintenance and repairs on old batteries become excessive. The consensus of opinion of builders and operators of ovens indicates that, with few exceptions, ovens older than 20 years become increasingly more difficult to maintain in good operating condition. The percentage of coke ovens over 20 years has increased steadily in the past 10 years, as shown in table 18. It is evident that new-oven construction will have to be increased rapidly in the next few years to compensate for obsolescence and old-oven failures if the number of efficient ovens is to be maintained at or above the present level.

At the close of the year, 562 new ovens were under construction, and contracts were pending on several additional batteries. Most of the new ovens under construction are replacements of old batteries, and the net gain in ovens will not be great.

Beehive Ovens.—The beehive-coke oven was the type of equipment used exclusively in the production of metallurgical coke in the United States before 1893. Development of the beehive industry reached its maximum stage in 1910, when over 100,000 ovens of this type were in existence. Since that year, the number has declined steadily, and the present-day importance of this type of equipment lies chiefly in its ability to provide a quick and inexpensive means of producing coke to meet peak demands. No better example of this service can be given than the record of production of metallurgical coke achieved by the beehives since the beginning of World War II. They have been furnishing 8 to 10 percent of the coke requirements, and the number in operation has ranged from 10,000 to 12,000 monthly. At the beginning of 1949, steel production was at extremely high levels, and the number of beehives active in the first quarter averaged 12,500. The reduction in blast-furnace operation in the second quarter affected a few beehive plants, and the number of active ovens declined. Initiation of a 3-day workweek in the bituminous-coal industry in July made it economically unfeasible to operate the ovens, and nearly all were closed, dropping to 344 ovens in October. The return of the miners to a 5-day workweek in December permitted a number of plants to resume operation, and the average number of active ovens increased to 4,079. Additional ovens were being reactivated at the close of the year to meet rising metallurgical coke requirements.

CAPACITY OF OVEN-COKE PLANTS

The potential annual coke capacity of oven-coke plants, as reported by operators, was 1 percent lower on December 31, 1949, than at the end of 1948. The decrease in capacity may be attributed to the following: (1) A large number of old batteries that require longer coking cycles and (2) the rebuilding of a number of old batteries that were dismantled and out of production at the end of 1949. The basis for calculating the potential annual coke capacity of a plant is the minimum coking time necessary to produce a coke with the qualities suitable for its intended use. For this reason, the potential capacity of a plant is subject to change from year to year, depending on the age and condition of ovens, character and quality of coal charged, type of coke required, and other related economic conditions. The potential capacity, reported by the Bureau of Mines, may differ, therefore, from the rated capacity estimated by the coke-oven builders at the time of construction. It is believed, however, that the potential capacity as shown in table 21 is a good measure of the practical operating capacity. Although 2,275,300 tons of coke capacity were completed in 1949, the total annual coke capacity decreased, indicating an extremely high rate of oven failures. At the end of the year, construction was

in progress on over 3,000,000 tons of coke capacity, but it is likely that most of this capacity will be replacement of old batteries.

Table 22 shows, by months, the ratio of coke production to capacity during 1949 and several prior years. The ovens were operated at an extremely high rate in the first quarter, declining in the second and third quarters, and dropping sharply in October because of the strikes in the iron, steel, and coal industries. Although the operating rate increased rapidly in the latter part of November and in December, it still was not as high at the close of the year as it was in the first quarter. Indications at the beginning of 1950 point to continuation of a high operating rate for some months to come.

TABLE 21.—Potential maximum annual coke capacity of all oven-coke plants in existence in the United States, 1937 and 1945–49

Year	Plants	Ovens	Potential maximum annual coke capacity (net tons)	Percent of change from 1937
1937	87	12,718	62,727,100

[1] Capacity of all ovens in existence, whether active or idle, based upon maximum daily capacity times days in month.

QUANTITY AND COST OF COAL CHARGED

The coke industry (oven- and beehive-coke operations) in 1949 was the largest individual consumer of bituminous coal in the United States for the second consecutive year, taking more than one-fifth of the total annual output. Strikes in the steel and bituminous-coal industries during 1949 materially reduced the consumption of bituminous coal, and the total quantity charged into slot-type and beehive-coke ovens decreased 15 percent from the record established in 1948, amounting to about 91,236,000 net tons. In addition to this figure, approximately 172,800 tons of anthracite were used for mixing with bituminous at nine coke plants. Under normal conditions, the monthly consumption of bituminous coal is quite uniform because of

the continuous nature of the coking process. However, interruptions in coking operations during 1949 because of the reasons given above caused the monthly output to fluctuate from a high of 8,658,200 tons in January to 2,474,000 tons in October, the lowest figure since May 1946.

The cost of coal constitutes the chief item of expense in the manufacture of coke. In the past 10 years coal costs have been rising steadily because of increases in mining and transportation charges. The average cost of coal at oven-coke plants in 1949, the highest on record, increased $0.39 per ton or 5 percent over 1948 and was 132 percent higher than the 1940 figure. A large part of the coal used at oven-coke plants is "long-haul" coal, which necessarily increases the cost at ovens. For this reason Rhode Island, California, and Massachusetts had the highest average costs, while West Virginia, which obtains coal from nearby fields, had the lowest. Details on the quantity and cost of coal at ovens, by States, are shown in table 24.

Although coal costs at beehive ovens in 1949 were the highest ever recorded in the industry, they were lower than at oven-coke plants because of their proximity to the mines. However, in recent years, some of the beehive operators have been burdened with an additional cost in trucking part, or in some cases all, of their coal requirements. The average cost of coal charged into beehive ovens was $0.31 per ton or 6 percent higher than the previous maximum in 1948 and 172 percent above the 1940 average. West Virginia beehive operators had the lowest cost, while Utah and Kentucky registered the highest.

PREPARATION AND SOURCE OF COAL

Washed and Unwashed Coal.—The quality of coke produced depends to a much greater degree upon the character and kind of coal carbonized than it does upon the oven design and carbonizing practice. The quality of coking coal varies widely from field to field and even within the same field. The wide adoption of machines to load coal and the decline in availability of the best quality coking coals in recent years have made it necessary to place more emphasis on the

blending and cleaning of the poorer coals in order to produce coke containing the desired chemical and physical qualities. One of the principal advantages of using clean coal is the resulting uniformity in the physical and chemical properties of the coke. Uniformity of coke is considered by blast-furnace operators as one of the most important factors in blast-furnace economy. The necessity for clean coal has resulted in the installation of a number of new cleaning facilities in the past several years, and the quantity of washed coal carbonized has increased steadily. In 1949, 38 percent of the bituminous coal charged into slot-type ovens and 20 percent of the coal for beehive ovens were washed, compared with 29 and 18 percent, respectively, in 1948. Coal cleaning to reduce its ash and sulfur content has been practiced by coke producers (according to available data) since 1890, when only 1 percent was washed. All coal mined and used for the manufacture of coke in Alabama and Colorado in 1949 was washed, most of Tennessee's, Oklahoma's, and about one-third of Pennsylvania's was also washed before being carbonized. Data in table 28 include coal cleaned at the mines by coal producers as well as that cleaned at the coke plants by coke-plant operators. Bituminous coal cleaned at the mines was used by 44 oven- and 7 beehive-coke plants and comprised 78 percent of the washed coal carbonized; the remainder (7,519,390 tons) was washed at 10 coke plants which have cleaning facilities at the ovens.

Sources.—Coal is the lifeblood of the coke ovens, and sources of supply are of paramount importance to the coke producers. The greatest concentration of coking coals in the United States and possibly in the world is found in the Appalachian region, extending from Alabama to Pennsylvania. Roughly 95 percent of all coal used in the United States for the manufacture of oven and beehive coke comes from States within this region. Relatively small deposits of coals suitable for the production of metallurgical coke occur in the Trinidad-Raton field of southern Colorado and northern New Mexico, the Sunnyside beds in the Castle Gate field of Utah, in Haskell and other counties in eastern Oklahoma, in Sebastian County in western Arkansas, and in Pierce and Kittitas Counties in Washington. The best high-volatile and medium-volatile coking coals are found in West Virginia, Pennsylvania, eastern Kentucky, and Alabama. The sources of low-volatile coking coals, which are very important for improving the physical properties of metallurgical coke, especially its strength, come principally from West Virginia and to a considerably lesser extent from central Pennsylvania, eastern Oklahoma, and western Arkansas. Origin and destination of coal used in the manufacture of oven coke are shown in detail in tables 29 and 30.

Many of the coke-producing companies, especially those connected with the iron and steel industry, own or control "captive" mines that supply them with coking coal. Annual reports submitted to the Bureau of Mines by oven-coke plant operators showed that more than 54 percent of the total quantity of coal carbonized in 1949 was obtained from such mines. Oven-coke plants associated with iron and steel works received 69,436,016 tons of coal in 1949, of which 42,432,013 tons, or 61 percent, was obtained from "captive" mines. Nonfurnace coke plants obtained 4,401,461 tons, or 27 percent, of the total receipts of 16,243,708 tons of coal from "captive" mines.

Blending.—As an important part of coal preparation, oven-coke plant operators mix or blend various types of coals before charging into the ovens. In many cases, a better coke can be obtained by a judicious blend of two, three, or more different coals than can be made from any one of the three by itself. Blending has several aims and considers many factors important to the oven-coke plant operators; the primary objective, of course, is to produce, economically, a quality coke satisfactory for the use intended. It also permits the use of coals that have good coking properties but otherwise may be objectionable from the standpoint of excessive ash, sulfur, or phosphorus content and that could not be used alone as a 100-percent charge. Thus, in addition to providing a means of controlling the quality and strength of the coke and the yield of coproducts, blending permits flexible operation at oven-coke plants and use of a wider variety of coking coal. In future, the problem of blending will be much greater, due to a shortage of the most desirable coals.[1]

[1] Savage, Philip S., The Blending of Coal to Improve Coke and Extend Coking Coal Resources: Blast Furnace and Steel Plant, vol. 37, No. 3, Mar. 1949, pp. 323–324 and 334.

Although all oven-coke plants mix or blend coals before charging them into the ovens, the mixing of coal of different volatile content was practiced at 77 oven-coke plants in 1949, of which 47 used high- and low-volatile coal; 25, high-, medium-, and low-; 2, high- and medium-; and 3, low- and medium-volatile. Of the plants that did not blend coals of different volatile content, 5 plants used straight high-volatile and 4, medium-volatile. The proportion of the different kinds of coals mixed before charging into ovens, where practiced, varies widely from plant to plant according to local conditions. Classification of all coal obtained by coke-plant operators in 1949 showed, however, that 65 percent was high-volatile; 12 percent, medium-volatile; and 23 percent, low-volatile.

TABLE 29.—Coal received for manufacturing oven coke in the United States in 1949, by fields of origin

[1] Computed by dividing production of breeze by coal charged at plants actually recovering.
[2] Included with "Undistributed."
[3] Not at liberty to publish.
[4] As reported; quantity produced but not used was undoubtedly greater. See Mineral Resources of the United States, 1922, pt. II, pp. 726–727.

SHIPMENTS BY RAIL, WATER, AND TRUCK

Table 33 shows, by method of movement, the quantity of coke and breeze shipped outside the producing plants in 1949. In the oven-coke industry the bulk of the coke produced is consumed in integrated metallurgical operations and therefore does not leave the producing establishments. For example, total shipments of oven coke in 1949 amounted to 37 percent of the total output. Railroads transported 89 percent of all oven-coke shipments; trucks, 4 percent; and boats, 7 percent. Nearly all beehive ovens are located at the coal mines; consequently, the coke must be loaded for shipment to points of consumption. In 1949, shipments of beehive coke totaled 3,323,682 tons, equivalent to 98 percent of the total beehive output. Railroads transported virtually all of the beehive coke shipped, as less than 1 percent moved by truck. No beehive coke was reported as moving on waterways in 1949, as the closing of the Weirton Coal Co.'s Isabella beehive plant in 1948 removed the last beehive plant that transported coke by barges.

DISTRIBUTION OF OVEN AND BEEHIVE COKE

Table 35 shows the quantity of coke and coke breeze distributed to each State in 1949, with a breakdown of the large coke according to principal end uses. Detailed statistics on this subject will be published and distributed by the Bureau of Mines in the form of a mineral market report.

The total quantity of coke distributed to consumers in 1949 was 63,462,233 tons, a 15-percent decline from the record movement in 1948. Deliveries to blast furnaces within the United States comprised 82 percent of the total shipments of all large coke; foundries received 4 percent, producer-gas and water-gas manufacturers 7 percent, other industrial purposes 3 percent, and residential or household heating 4 percent. Pennsylvania was the largest user of coke, with 25 percent of the total, followed by Ohio and Indiana, with 16 and 10 percent, respectively. Furnace coke was used in 18 States in 1949; however, 76 percent of the total was used by 5 States—Pennsylvania, Ohio, Indiana, Illinois, and Alabama. Coke for foundry use was shipped to all States. Coke was used for the manufacture of producer gas in 8 States and for producing water gas in 27. The consumption of coke for other industrial purposes is widespread, and all but one State used coke for miscellaneous industrial purposes. Coke for residential and commercial heating has been declining rapidly in recent years because of competition from oil and gas and also because of the demand for industrial coke.

TABLE 35.—Oven and beehive coke and breeze distributed to each State in 1949, in net tons

[Based upon reports from all United States producers showing destination of coke used by producer or sold in 1949. Does not include imported coke, which totaled 277,507 tons in 1949]

Consuming State	Coke							Coke breeze

CONSUMPTION OF COKE

The indicated consumption of coke in the United States in 1949 declined 14 percent from the record established in 1948 owing largely to work stoppages in the bituminous-coal and iron and steel industries. The indicated consumption, as calculated by the Bureau of Mines, allows for imports, exports, and changes in producers' stocks but does not take into account stocks held by consumers. However, as con-

sumers' stocks seldom vary widely from year to year, the indicated consumption of coke is a good barometer of the industrial activity of the country, as approximately 95 percent of the total production each year is used for industrial purposes. The principal branch of coke consumption is the smelting of iron ores in blast furnaces, which in the past 10 years have utilized between 70 and 80 percent of the annual output. One of the features in the consumption of coke in blast furnaces in 1949 was the improvement in their fuel efficiency. According to data compiled by the American Iron and Steel Institute, the quantity of coke required to produce 1 net ton of pig iron (including ferro-alloys) declined 41.4 pounds, or 2 percent, from the 1948 figure. This improvement could be attributed to several factors, among which was improvement in the quality of coking coal used in the manufacture of coke in 1949. Fuel efficiency should continue to improve in future because of technologic advancements in blast-furnace practice, better selection of coal, and the construction of more coal-preparation plants. The quantity of coke consumed for all other purposes (in foundries, nonferrous smelting, chemical processes, manufacture of producer gas and water gas, and residential heating) dropped 19 percent from 1948. This was due largely to a sharp reduction in foundry-coke requirements and to further curtailment in sales of coke for residential heating.

Statistics on the disposal, by major uses, of oven and beehive coke, as reported by producers, are given in tables 38 and 39. These data show the extent of the markets for coke and the magnitude of the iron and steel industry, the largest individual consumer. The proportion of oven coke reported by producers as used in integrated blast-furnace operations and sales to financially affiliated companies for blast-furnace use amounted to 76 percent of the total output in 1949. Even this high percentage does not indicate the full extent of the interrelationship of the oven-coke and steel industries, as 80 percent of all oven coke produced in 1949 was made in ovens owned and operated by steel companies. On the other hand, the nonfurnace or merchant oven-coke plants supply the bulk of the coke used for all other industrial purposes, as well as that used for residential heating. In 1949, merchant oven-coke plants supplied 83 percent of foundry-coke shipments, 87 percent of the coke classified as "other industrial," and 82 percent of the total sales for residential heating.

TABLE 36.—Coke consumed in manufacture of pig iron and for other purposes in the United States, 1913, 1918, 1937, and 1947–49, in net tons

Year	Total production	Imports	Exports	Net change in stocks	Indicated United States consumption [1]	Consumed by iron furnaces [2]		Remainder consumed in other ways

[1] Comprises 80,395 tons valued at $1,230,026 used in foundries; 790,910 tons, $9,538,902 to make producer gas; 1,313,785 tons, $16,167,896 to make water gas; and 256,298 tons, $3,574,475 for other purposes.

[2] Includes 10,656,809 tons valued at $135,672,369 sold to financially affiliated companies.

[3] Included with "Undistributed."

[4] Includes 52,433 tons valued at $1,158,472 sold to financially affiliated companies.

[5] Includes 721,076 tons valued at $9,867,867 for manufacture of water gas and 192,713 tons, $2,573,912 for other industrial use sold to financially affiliated companies; and 1,267,895 tons, $17,135,440 for manufacture of water gas sold to other consumers.

Insufficient oven-coke capacity by the iron and steel industry has made it necessary for several of the large steel companies to lease and operate beehive-coke ovens to augment their supplies of blast-furnace coke. For example, in 1943, when beehive-coke production reached its wartime peak, the quantity used by producers or sold to financially affiliated companies for blast-furnace use represented about 26 percent of the total output. In 1949, however, the proportion of furnace coke used by the producers or sold to affiliated interests had risen to 34 percent. Total shipments of beehive coke to blast furnaces amounted to 84 percent of the total deliveries, iron foundries received 6 percent, other industrial (including water-gas manufacture) 9 percent, and residential heating less than 1 percent.

[1] Includes 1,094,907 tons valued at $12,324,470 sold to financially affiliated companies for blast-furnace use.
[2] Included with "Undistributed."
[3] Includes 554 tons valued at $8,045 sold to financially affiliated companies for other industrial use and 114,973 tons, $1,609,798 for manufacture of water gas sold to other consumers.

STOCKS OF COKE AND COKING COAL

Coke.—Producers' stocks of oven coke on December 31, 1949, increased 10 percent over the previous year. The increase was due largely to the increase in stocks of "domestic and other coke" at merchant plants, as stocks of metallurgical coke at furnace plants decreased slightly. Normally, furnace plants carry only a few days' supply of coke because of the vertical integration of their operations. Merchant plants more often find it necessary to stock coke, especially the domestic sizes. Storage is held at a minimum because of degradation in size, and rescreening before shipment is necessary. The total quantity of oven coke stocked at producers' plants on December 31, 1949, was equivalent to but 9.6 days' production at the prevailing rate. Producers' stocks of beehive coke, which usually are even smaller than stocks carried by oven-coke plants, increased 61 percent over the previous year and totaled 52,898 tons.

Coal.—Adequate stocks of bituminous coal at oven-coke plants are necessary because of the continuous nature of the carbonizing process. Operators usually try to maintain at least a 30 days' supply to assure full-scale operations in case of disruption in the flow of coal to the

plants. In anticipation of mine shut-downs, coke-plant operators built up their inventories of coal in the first half of the year to an all-time record on May 31, 1949, when nearly 16,000,000 tons, or about 59 days' supply, were carried in reserve. Stocks remained at this level during June but started to decline in July and by December 31, 1949, had dropped to less than 10,000,000 tons, or 38 days' supply.

VALUE AND PRICE

The term "value," as used in this report, represents the value of the coke at the ovens as reported by producers. For that part of the output sold, the value is the amount received for the coke f. o. b. ovens. However, the greater part of the coke produced in the United States is made in ovens operated by corporations which not only mine the coal used in the manufacture of coke but also operate blast furnaces and steel mills consuming the entire output of their ovens. Under such conditions, fixing a value for coal charged and for coke produced is governed by established accounting procedures. For example, at some plants the cost of coke to the furnace department equals the cost of production; at others, a margin of profit is added; or the reported value is based on what the coke would cost if purchased. The line between sales and interdepartmental transfers is difficult to draw among such affiliated interests, as a large part of the furnace coke reported as sold actually goes to iron furnaces that are in some way connected with the coke producers. The average value of all coke produced, measured in this way, was $13.24 per ton, the highest figure ever recorded and a gain of 7 percent over 1948 (table 44).

The average price received for each ton of coke sold f. o. b. ovens (merchant sales) in 1949 established a new record and was 4 percent over the 1948 figure. Table 45 shows average receipts from sales classified by uses and by States. It will be noted that prices vary notably with the distances from the mines. Thus, the highest average prices are those reported for the New England and Lake Dock States, where the coal must be hauled great distances.

TABLE 44.—Average value per net ton of coke produced and average receipts per net ton from coke sold (merchant sales) in the United States, 1937 and 1945–49

Year	Value per ton produced			Receipts per ton sold [1]

FOREIGN TRADE [2]

Imports.—Statistics on United States imports include both coal coke and petroleum coke, although the two varieties are segregated in export statistics. Imports of coke in 1949 increased 72 percent over 1948; but the total quantity involved was small in comparison with the national output, and its use was restricted generally in the areas near the points of entry. All of the coke imported in 1949 came from Canada, the bulk of which entered through the Buffalo, Michigan, and Montana-Idaho customs districts. The coke entering through the Montana-Idaho customs district was probably used for smelting nonferrous metals, while that coming in by way of Buffalo and Michigan was used principally for residential heating. Undoubtedly, some of the coke that entered through the Buffalo gateway was petroleum coke and was used for the manufacture of carbon electrodes.

[1] All from Canada 1947 and 1949; 1948: Canada 160,795 tons ($2,096,063) and Netherlands 605 tons ($14,212).

Exports.—Exports of coke to foreign countries other than Canada are normally small and have little effect on domestic supplies. Shortages of coke within continental United States during and after World War II made it necessary to place Government control on exports of metallurgical coke, the grade in shortest supply. Exports of metallurgical coke in 1949 to Western Hemisphere countries except Canada were limited to quotas. A quota of 15,000 long tons was placed for South American countries in the first quarter of 1949; it was raised to 20,000 tons in the second and 50,000 tons in the third quarter, and quota limitation was removed at the beginning of the last quarter. The demand for metallurgical coke in the United States throughout the year, however, made it impossible to ship the quotas established, and the total quantity of coke exported to all countries, including

[2] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

[1] Revised figures.

Canada, declined 22 percent from 1948. Canada received 78 percent of the coke exported, most of which moved through the Michigan and Buffalo customs districts. Exports to Mexico more than doubled and represented 16 percent of the total.

TECHNOLOGY

Research and scientific work on coal carbonization in 1949 was high-lighted by the survey being conducted by the Bureau of Mines on coking-coal reserves. The Bureau of Mines program on the appraisal of coking-coal reserves has three objectives. These are: (1) An inventory of minable coking-coal reserves; (2) the basic washing characteristics of these coals; and (3) their basic coking characteristics. This program was initiated in 1948, and progress made in 1949 was summarized recently.[3] Results of other studies on coal carbonization made by Bureau of Mines engineers were published in 1949.[4]

The Fourteenth Annual Report of Research and technologic work conducted by the Bureau of Mines on coal and coal products from July 1, 1948, to July 1, 1949, was released in June 1950.[5] This report gives a brief résumé of the special studies made by Bureau engineers on the carbonizing properties, plasticity, expansion, and oxidation of coal. For details concerning the individual studies, the report lists the original publication and, in addition, presents results of research that have not been already published.

The Mellon Institute of Industrial Research, in its Thirty-seventh Annual Report, covering the fiscal year ended February 28, 1950, summarized studies made on problems relating to coke-plant technology, coke, and coal chemicals.[6]

The United International Research, Inc., of Newark, N. J., announced a new low-cost process for producing cresol synthetically from toluene, using a boron catalyst. In this process toluene vapors are bubbled continuously into a reaction vessel containing a boron catalyst dissolved in sulfuric acid. The co-called toluene-boron complex is hydrolyzed with steam or boiling water to yield a mixture of about 80 perc para-, 10 percent meta-, and 10 percent ortho-cresol. Final separatio of cresol from the hydrolysis mixture is aided by stirring in some toluene. After washing, the toluene and cresol are separated by fractionation, and water-white cresol, above USP standards, is obtained as a product. Yield is 80 to 90 percent of cresol, with a residue of cresol resorcinal that may have pharmaceutical uses.[7] A comprehensive review of significant technical developments throughout the world in the field of coal carbonization was published recently.[8] This review summarized studies on raw materials, products and by-products of coal carbonization, oven- and retort-equipment improvements, and procedures for analysis and testing.

WORLD PRODUCTION

Coke is a basic industrial fuel, and production therefore is concentrated largely in the highly industrialized nations. Estimated world production in 1949 was 2 percent higher than in 1948; but it was 23,828,000 tons, or 13 percent, below the record wartime output in 1943. The rise in production of coke in 1949 in many countries that suffered severe war damage indicated that progress was being made in industrial production. The United States has dominated the world in coke production since 1938 and supplied 35 percent of the world total in 1949. Little authentic information has been available on production in the Soviet Union since 1937, but estimates for 1949 place this country next to the United States. Germany assumed temporary world leadership in coke production in 1938; but war damages to coke plants and territorial changes have reduced the output of German coke greatly, and in 1949 the quantity produced in western Germany represented 14 percent of the total. Other important coke-producing countries in 1949 were Great Britain, France (including the Saar), Czechoslovakia, and Poland, which combined furnished 23 percent of the total. The accompanying table contains information on world production so far as data are available.

[1] Excludes gas-house coke.
[2] Coke is also produced in New Zealand, but data are not available.
[3] Data not available; estimate by senior author of chapter included in total.
[4] Estimate.
[5] Exports.
[6] Areas designated as Free China during the period of Japanese occupation.
[7] Fiscal year ended Mar. 31 of year following that stated.
[8] Includes Silesian production.
[9] British and American zones only.
[10] Preliminary data for fiscal year ended Mar. 31 of year following that stated.
[11] Preliminary figures.
[12] Production of Siberia and Urals only.
[13] In Great Britain production of gas-house coke is especially important: 10,770,130 tons in 1938, averaged 11,000,000 tons per year 1941–45, and increased 15 percent in 1946–47 and 25–30 percent in 1948–49.

COAL-CHEMICAL MATERIALS

GENERAL SUMMARY

The coke industry, in addition to providing American industry with special fuels, furnished chemical raw materials that have been increasing in importance in recent years. Gas, ammonia, crude light oil, and tar are the principal coal-chemical materials, but the term also includes fractions and individual compounds that are recovered therefrom by a chain of chemical processes. Coal chemicals enter many industries and pass from industry to industry as the product of one becomes the raw material for another in the production of a final commodity. For this reason, there exists a definite relationship between the coke industry and countless other industries that depend directly or indirectly on the former as a source of supply of essential chemical raw materials. Although coke-oven gas is a potential source of chemical raw materials, such as hydrogen, ethylene, etc., it is not processed to any appreciable extent in this country, and virtually all of the output is used as fuel for industrial and residential purposes. The increased demand during and since World War II for products made from ammonia, crude light oil, and tar stimulated interest in their manufacture, and coke-plant operators have been constantly developing special technical processes, equipment, and operating technique for their economical production. Evidence of the expansion in refining facilities at coke plants is given by the increased quantities of crude light oil and tar processed in 1949 as compared with 1939. In 1939 about 163,947,000 gallons of crude light oil and 111,783,000 gallons of crude tar were processed by coke-plant operators, whereas in 1949 the figures were, roughly, 220,888,000 and 166,669,000 gallons, increases of 35 and 49 percent, respectively. The increase in raw materials processed has naturally increased the quantities of pure products, such as benzol, toluol, and xylol, produced at coke plants during this period. In spite of the increased production of these products, the revenue obtained from the sale of coal-chemical materials has not kept pace with the increase in coal costs nor with the value credited to coke production. Thus, while average coal costs increased 127 percent in 1949 over 1939, and the average value of coke produced increased 176 percent, the increase in revenue from the sale of all coal-chemical materials per ton of coke amounted to but 11 percent. In other words, the revenue obtained from the sale of coal chemicals was equivalent to 22 percent of the total value of all products compared with 36 percent in 1939.

At the beginning of 1949, supply and demand of most of the basic coal chemicals were in close balance, but as industrial activity began to slacken in the second quarter of the year, requirements were slightly reduced. The change in demand for the chemical grades of benzene (benzol) was one of the outstanding developments during the year. Production of the chemical grades of this commodity was cut back slightly in the latter part of March, and a larger proportion of "motor grade" was recovered. In the ensuing months, the output of "motor benzol" increased substantially at the expense of the chemical grades. However, the strikes in both the bituminous-coal and steel industries during the latter part of the year affected the operation of coke plants and curtailed the output of all coal chemicals. This

development reversed the production pattern of benzol again as demand for the chemical grades increased and coke-plant operators found it necessary to recover as much of these grades as possible. Decreased production of crude naphthalene and creosote oil at coke plants during 1949 may be attributed to (1) a slackening in demand and (2) the substantial quantities of these materials imported from abroad. The increased production of synthetic ammonium sulfate eased the supply situation of this nitrogenous fertilizer material, and sales of coke-oven sulfate lagged considerably behind production. The accompanying tables contain detailed statistics on the production and sales of the various coal-chemical materials in 1949.

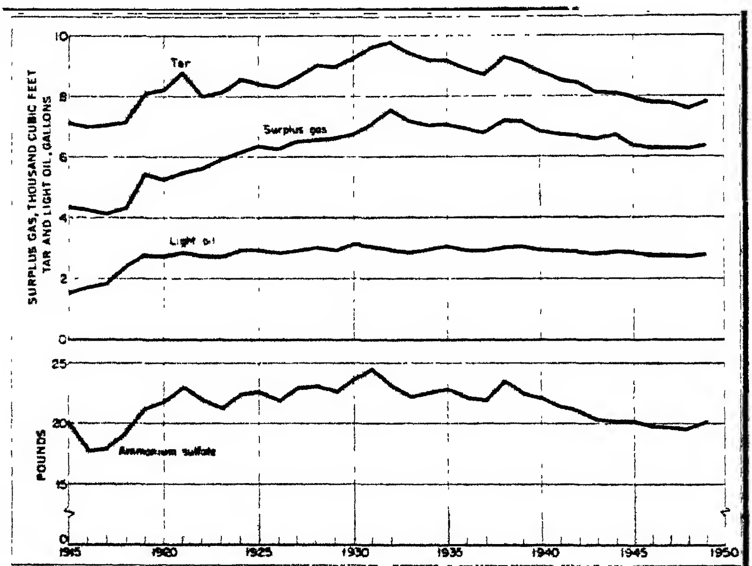

FIGURE 2.—Average yield of principal coal-chemical materials per net ton of coal carbonized in coke ovens, 1915–49. Yields of light oil and ammonium sulfate equivalent represent average for plants recovering these products.

COKE-OVEN GAS

High temperature slot-type coke ovens are primarily producers of specialized forms of fuel. In addition to the main product—coke—another major fuel is recovered in the form of gas. At some plants its importance ranks scarcely second to that of coke itself. In the high-temperature carbonizing process, approximately 10,000 to 12,000 cubic feet, or 17 percent by weight, of the coal carbonized is recovered in the form of fuel gas. Usually, about 37 percent of the total volume of the gas produced is used to heat the ovens, and the remainder (surplus gas) is piped to affiliated metallurgical operations and neighboring industries, and through city mains for public distribution. As a source of revenue to coke-plant operators, it ranks next to coke and since the early 1920's has furnished about 50 percent of the total revenue derived from all coal-chemical materials. The iron and steel industry is the largest consumer of coke-oven gas and in 1949 used

about two-thirds of the surplus gas in metallurgical furnaces or as boiler fuel. Public utilities are the second largest consumer, usually taking about 30 percent of the total. The balance is sold by the producers themselves for industrial purposes, although some of the coke-oven gas going through city mains is used for industrial purposes. Furnace plants produce and distribute by far the larger amount of coke-oven gas; however, merchant plants supply the larger part of the gas distributed through city mains. Public utilities or city gas plants, built primarily to supply gas, received the largest unit value for their product.

CRUDE COAL TAR

Crude-tar production declined 9 percent from 1948, in spite of a slight increase in yield. Tar is used as a fuel, or it may be processed into various useful tar products, depending on business and economic factors. In the early days of the oven-coke industry, virtually all of the tar produced was used as fuel. The Allied blockade during the early stages of World War I shut off our supplies of dyes, intermediates, and other synthetic organic chemicals from abroad and made it necessary for this country to process its tar to make the chemicals formerly imported. The growth of the synthetic organic chemicals industry in the United States has been rapid, and one of the principal raw materials used to make the finished chemical products has been crude coal tar. Plastic, pharmaceutical, paint, dye, and other industries have expanded greatly, absorbing larger and larger quantities of tar, reaching a point in 1946 when only 11 percent of the tar produced was used as fuel. The cost of fuel oil, which can be burned in place of tar, determines whether tar can be sold or processed advantageously, and the quantities burned have varied somewhat in the past several years. Thus, in 1949, 25 percent of the total tar production was burned and 75 percent was processed, either in facilities owned and operated by coke producers or by tar refineries operated independently of coke-oven operations.

Creosote oil, a tar derivative used in the United States mainly for wood preservation, is the principal product made by coke-plant operators and usually supplies about 50 percent of the revenue received from the sale of all tar derivatives. Production of this material declined 30 percent from 1948, largely because of a lower demand and of increased supplies from abroad. The quantity imported (33,395,011 gallons) was nearly one-third greater than the output reported by coke-oven operators. Tar-acid-oil production declined slightly from 1948 but ranked next to creosote oil as a revenue producer, furnishing 36 percent of the total revenue derived from sales of tar derivatives. Details on production and sales of cresols, cresylic acid, anthracene, and other derivatives cannot be disclosed, as less than three producers reported these products to the Bureau of Mines. Virtually all of the pitch output, which decreased 15 percent from 1948, was used by the producers. The soft- and medium-melting-point pitches are cut back (usually with virgin tar) to the desired viscosity and used as metallurgical fuel. The hard pitch produced at several plants is pulverized and mixed with the coal before charging into ovens to improve coke quality.

COKE-OVEN AMMONIA

Total production of coke-oven ammonia (NH_3 equivalent of all forms) in 1949 decreased 9 percent from 1948. Ammonia is recovered at coke plants either as its water solution (ammonia liquor) or as a crystallized ammonium sulfate. In 1949, 80 of the 86 active plants recovered ammonia, 64 of which made ammonium sulfate and 18 ammonia liquor (2 plants produced both sulfate and liquor). Purchased synthetic anhydrous ammonia was converted into sulfate at 5 coke plants in 1949. This practice was adopted by coke-oven operators in the middle of 1947 to alleviate the shortages of nitrogenous fertilizers that have existed since the end of the war. Figures on synthetic sulfate have been tabulated separately by the Bureau to maintain the series on coke-oven sulfate proper. In 1949, however, the production of synthetic ammonium sulfate increased tremendously because of the construction of several huge plants by primary producers of synthetic ammonia. The rise in production of synthetic sulfate eased the supply picture considerably; and coke-oven sulfate shipments dropped below production, so that stocks at the end of the year were nearly three times as large as they were at the beginning. Although prices did not change during the year, indications in the first quarter of 1950 pointed to a decrease in prices from the high level that has prevailed since the end of the war.

CRUDE LIGHT OIL AND DERIVATIVES

Slot-type coke ovens are the principal source of crude light oil from which benzene and its homologs—toluene, xylene, etc.—are recovered. The potential yield of crude light oil per ton of coal varies widely from plant to plant, depending on the quality of coal charged, design and condition of ovens, oven temperatures, and kind of scrubbing equipment. In 1949, the yield of crude light oil ranged from 1.50 to 4 gallons per ton and averaged 2.77 compared with 2.73 in 1948. Most of the light oil produced at coke plants is processed by the producers, and only 3 percent of the output was shipped to independent refiners. Total output in 1949 decreased 11 percent from 1948 to 228,754,333 gallons. Production of benzol (all grades), the principal constituent of light oil, decreased 10 percent from 1948. About 85 percent of the benzol produced was refined into the 1° and 2° grades, although it is known that some of the benzol classed as motor was not actually used as fuel but was sold to tar refineries for processing into chemical grades. The development of new applications for benzol derivatives in synthetic rubber, nylon, insecticides, detergents, and other uses has increased the requirements for industrial benzol far above the quantities used before World War II. As the uses of the new products are exploited, requirements for industrial benzol will undoubtedly increase substantially over the current level and even reach beyond the ability of the coke industry to satisfy with its existing capacity. The expanding markets for pure benzol has stimulated interest in its manufacture from petroleum and production on a commercial scale was reported in 1949.[9]

Value of all coal-chemical materials sold			256,720,731		

[1] Includes products of tar distillation conducted by coke-oven operators under same corporate name.
[2] Softening point less than 110° F. Includes some medium pitch-of-tar reported by 2 producers.
[3] Softening point over 160° F.
[4] Cresols, cresylic acid, fuel oil, pitch coke, refined tar, and tar paint.
[5] Excludes value of sulfate made from purchased synthetic ammonia.
[6] Excludes sulfate made from purchased synthetic ammonia.
[7] Includes gas used for heating ovens and gas wasted.
[8] 220,868,075 gallons refined on premises to make derived products shown.
[9] Benzol still residue, dicyclopentadiene, orthoxylene, and vented vapors.
[10] Ammonium thiocyanate, picolines, secondary oil, and sodium prussiate.

Toluol production declined slightly from the 1948 output but was about 50 percent higher than the average annual prewar output in 1935–39. Unlike benzol, which at the present is virtually all recovered from coal carbonization, large quantities of toluol are made from petroleum. Toluol is used extensively as a solvent, particularly in the field of synthetic plastics, and it is also used for synthesizing a number of other chemicals, such as benzoic acid. In wartime its importance is derived from its use in the manufacture of explosives and also for enriching aviation gasoline. Prices of toluol did not change materially from 1948, although they were considerably less than the wartime average. Production and prices of xylol and solvent naphtha showed only minor changes when compared with 1948.

TABLE 50.—Coal equivalent of coal-chemical materials produced at oven-coke plants in the United States, 1913, 1914, 1918, 1937, and 1947–49

Year	Quantity of coal-chemical materials				Estimated equivalent in heating value (billion B. t. u.)					Coal equivalent	
	Coke breeze (thousand net tons)	Surplus gas (billion cubic feet)	Tar produced (thousand gallons)	Light oil produced (thousand gallons)	Coke breeze	Surplus gas	Tar	Light oil	Total	Net tons	Percent this forms of coal made into coke

COKE OVENS OWNED BY CITY GAS COMPANIES (PUBLIC UTILITIES)

The accompanying table compares the activities of coke plants operated by gas utilities with those not owned by city gas companies for 1948 and 1949. This classification is maintained by the Bureau of Mines in the interest of those who may wish to follow coal carbonizing at public utility plants and also to show their relative value to the coke industry as a whole.

Normally, maximum production of gas of proper analysis is the primary objective of these plants; however, the extremely heavy demand for industrial coke during and since the end of World War II has caused many operators to place a greater emphasis on coke, and in 1949 more than a million tons of metallurgical coke from this group were shipped to iron blast furnaces and foundry cupolas. Although the volume of coke production has not decreased markedly in recent years, the number of operators has been declining steadily because of the substitution of natural gas for coke-oven gas in certain areas. In 1949, the Lynn Gas & Electric Co., Lynn, Mass., discontinued operating its oven-coke plant, leaving but 12 city-gas coke plants in operation at the end of the year. Several other companies are planning the

substitution of natural gas for coke-oven gas in 1950 and will be closed down unless the plants can be disposed of to other interests. City gas plants in 1949 contributed 6 percent of the total production of oven coke, gas, and tar, 4 percent of the crude light oil, and 5 percent of the ammonia.

Copper

By Charles White Merrill and Helena M. Meyer

GENERAL SUMMARY

FOR several months after the first quarter of 1949 supplies of copper exceeded demand considerably in the United States. As a consequence, prices dropped, stocks rose, and production was curtailed. These months marked the first protracted period when supplies were more than adequate for all needs since the beginning of World War II. The recession in the copper industry accompanied the general industrial reaction. In recovering substantially in the late months of the year, copper followed the pattern for industry in general but made greater advances than many other commodities. For the year as a whole, mine production of copper dropped 10 percent, refinery output from domestic and foreign primary materials decreased 16 percent, apparent consumption of new copper fell 12 percent, total consumption of copper in the form of metal declined 17 percent, and the average quoted price for electrolytic copper was 13 percent less than in 1948.

At the beginning of 1949 demand considerably exceeded supply owing partly to the work stoppage at the Kennecott Copper Corp. Utah Copper mine, West Mountain (Bingham) district, Utah, largest producer in the United States, from October 24, 1948, to February 8, 1949. Because of this strike, production in 1948 was about 50,000 tons less and in 1949, 35,000 tons less than had been anticipated. Demand for copper was heavy during the first quarter, when according to records of the Copper Institute, 305,085 tons were delivered to customers; deliveries in the second quarter totaled 154,353 tons, little more than half as much. In the third quarter deliveries advanced to 239,170 tons and in the fourth to 332,987 tons, the highest quarterly total for the year. Refined-copper production was affected adversely in 1949 by the strike from June 30 to October 28 at the Carteret, N. J., plant of the American Metal Co.

The average quoted price for electrolytic copper, f. o. b. refinery, was 23.2 cents a pound from August 10, 1948, until the end of March 1949, when a decline of ½ cent a pound marked the beginning of a major downtrend. By the end of April the price was 19.7 cents and by the end of June 15.7 cents. An improvement in demand caused the price to turn upward in early July, and on November 3 it rose to 18.2 cents, where it continued beyond the year end.

After the collapse in demand and price in the second quarter, domestic production dropped. Mine output was 184,324 tons in January–March, 201,509 tons in April–June, 170,624 tons in July–September, and 196,293 tons in October–December. The curtailment in output, initiated on a large scale in May, was brought about chiefly by a reduction in the workweek from 48 to 40 hours at the leading copper-producing properties rather than by numerous mine closures, although some small mines ceased to produce. By the end

of 1949, operation on a 48-hour basis had been resumed at most properties.

Receipts of unmanufactured copper established a new high record in 1949, exceeding the previous peak in 1948 by 9 percent. Continuation of large imports despite the drop in demand caused dissatisfaction among the domestic mining companies that have no large foreign mining subsidiaries. In the late months of the year, after demand resumed large proportions, imports of substantial quantities of copper were again needed to fill total domestic requirements.

Legislation suspending the excise tax of 4 cents a pound on copper imported into the United States called for resumption of the tax after March 31, 1949, but the suspension was continued to June 30, 1950, by a bill signed by President Truman on March 31. On February 14, Chile's acceptance of the General Agreement on Tariffs and Trade, concluded by the United States and 22 other countries at Geneva on October 30, 1947, made a cut from 4 to 2 cents in the excise tax on copper effective when the tax suspension ended. As a result of the reduced demand for copper in the second quarter of 1949, there was agitation in Congress for withdrawal of the tax suspension, but the year closed without such action having been taken. Efforts to pass mine subsidy legislation in 1949 likewise were unsuccessful.

Exports of refined copper, by far the most important class, decreased 3 percent in 1949, marking a continuation of the downtrend in 1948.

Effects of the devaluation of the British pound and of other currencies, in mid-September, on world trade in copper and manufactures of copper, as well as on trade in other products, may not be determined for a long time.

The report of this series for 1948 outlined the plans in progress or prospect for major expansion or maintenance of current production rates. Construction on the "greater Butte project" of the Anaconda Copper Mining Co. proceeded on schedule through the first quarter of 1949; it was then suspended temporarily until the fourth quarter, when construction of surface facilities and preparations for mining were resumed. Construction of the new plant for treatment of sulfide ores at the Chuquicamata mine of the Chile Exploration Co., subsidiary of the Anaconda Copper Mining Co., proceeded throughout 1949, and the schedule calls for bringing the plant into operation in the first half of 1952. Total expenditures on this plant to the end of 1949 were $23,032,661, of which $19,493,338 was expended in 1949.

Exploration in 1949 at the White Pine, Mich., property of the Copper Range Co. added 50,000,000 tons of positive plus probable ore to reserves. Total reserves at the end of 1949 were 249,610,000 tons, containing 1.115 percent copper. Drilling at the property continued.

Construction of the new electrolytic refinery of the Kennecott Copper Corp. at Garfield, Utah, progressed during the year, and production of refined copper was expected soon after mid-1950. The planned capacity of 12,000 tons monthly, it is said, can readily be raised to 16,000 tons. Development and stripping operations preparatory to the initiation of open-pit mining at the Ray, Ariz., Division of Kennecott progressed in 1949 to a point permitting production of about 2,500 tons of pit ore a day. In mining part of the remaining tonnage

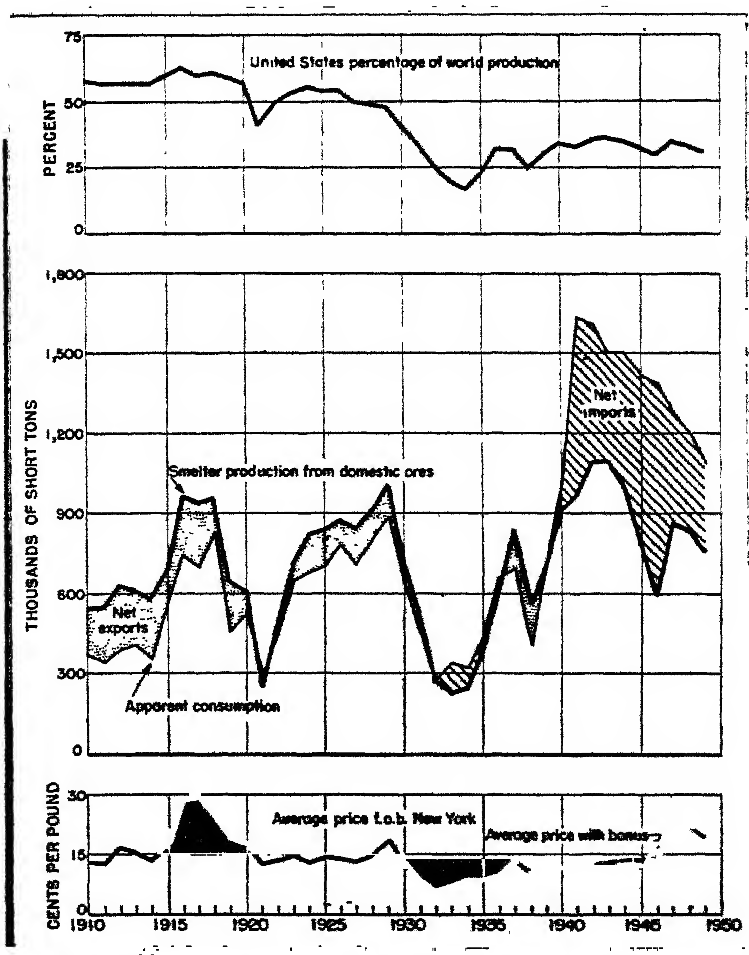

FIGURE 1.—Trends in production, consumption, and price of copper in the United States, 1910–49.

in the No. 1 ore body by open-cut methods, the company plans to expand daily mine and mill capacity from 6,000 to 15,000 tons of ore. Block caving will continue to be used at No. 2. Facilities at the Hayden, Ariz., smelter of the American Smelting & Refining Co. are being extended to treat the additional tonnages of concentrate.

The new smelter of the Phelps Dodge Corp. under construction at Ajo, Ariz., in 1949 will be ready for operation by the middle of 1950, if the current schedule is maintained. In recent years the New Cornelia pit at Ajo has been expanded [1] to permit increased production from about 22,000 to 28,000 tons of ore a day.

At the Inspiration Consolidated Copper Co. property in Arizona, open-pit operations were begun in 1948 to treat ores too thin and in

[1] Engineering and Mining Journal, Phelps Dodge Projects Assure Copper for Tomorrow: Vol. 150, No. 7, July 1949, p. 98.

some places too low grade to be mined by the block-caving system solely used previously at the mine. In 1949, the first full year of open-pit mining, 44 percent of the tonnage of copper ore mined was produced by this method.

Work at the San Manuel, Ariz., property consisted in sinking No. 1 shaft 1,145 to 1,270 feet by December 31, 1949 and No. 2 shaft 798 to 988 feet at the year end. Following completion of shaft sinking the program provides for lateral development at one or more levels. Preliminary designs of plant, townsite, and necessary transportation facilities are in course of preparation. Evidently no effort was made to extend the already reported developed reserves of 462,784,500 tons of ore, averaging 0.782 percent copper.

World mine output of copper was about 4 percent lower in 1949 than in 1948. The over-all decrease was brought about chiefly by declines in the United States, Chile, and Belgian Congo, too large to be counterbalanced by gains in Northern Rhodesia and Canada.

Salient statistics of the copper industry in the United States, 1940–44 (average) and 1945–49, in short tons

[1] Includes old tailings.
[2] Data include copper imported for immediate consumption plus material entering country under bond.
[3] Revised figure.
[4] Total exports of copper, exclusive of ore concentrates, composition metal, and unrefined copper. Exclusive also of "Other manufactures of copper," for which figures of quantity are not recorded.
[5] Excludes rods.
[6] Exclusive of bonus payments of the Office of Metals Reserve; Premium Price Plan covered the period February 1, 1942, to June 30, 1947, inclusive.

Northern Rhodesian operations continued to be hampered by inadequate transportation facilities and a consequent shortage of coal. More intensive wood burning in 1949, however, permitted increased production compared with 1948. Production in Belgian Congo was curtailed owing to a shortage of power caused by a drought and by insufficient coal. Initial production at the Quemont and East Sullivan mines in Canada was a factor in the increased output for that country. All three major producers in Chile shared the decrease in the production for that country compared with 1948.

The following Bureau of Mines reports of investigations, published recently, relate to copper in whole or in part.

4431. Copper-Nickel Deposits of the Stillwater Complex, Stillwater and Sweetgrass Counties, Mont.
4492. Scarlet Copper Mine, Randolph County, N. C.
4494. Copper-Bearing Pyrite Ores, Pyriton, Clay County, Ala.
4504. Keystone and St. George Copper-Zinc Deposits, Cochise County, Ariz.
4544. Rambler Copper Mine, Albany County, Wyo.
4579. Boston Consolidated Copper Mine, Salt Lake County, Utah.
4612. Chloride Volatilization and Other Tests on a Gold-Copper Ore.
4617. Table Mountain Copper Deposit, Churchill County, Nev.
4665. Magruder and Chambers Copper Deposits, Lincoln and Wilkes Counties, Ga.
4666. Perkiomen Creek Copper Deposits, Montgomery County, Pa.
4691. Tapley Copper Deposit, Hancock, Maine.
4694. Cove Meadow Copper Deposit, Humboldt, Nev.

The following Bureau of Mines information circulars likewise discussed copper.

7501. Safety Practices at United Verde Mine, Phelps Dodge Corp., Jerome, Ariz.
7502. Mining Methods and Costs at the Atwood Copper Mine, Lordsburg Mining District, Hidalgo County, N. Mex.
7536. History of Premium Price Plan for Copper, Lead and Zinc, 1942–47, by H. E. Olund and S. A. Gustavson.
7548. Safety Practices in Churn Drilling at Morenci Branch, Phelps Dodge Corp., Morenci, Ariz.

DOMESTIC PRODUCTION

Statistics on copper production may be compiled upon a mine, smelter, or refinery basis. Mine data are most accurate for showing the geographic distribution of production; smelter figures are better than mine figures for showing the actual recovery of metal and more accurate than refinery figures for showing the source of production; and refinery statistics are best for showing recovery of metal but indicate only in a general way the source of crude materials treated. Mineral Resources of the United States, 1930, part I (pp. 701–702), discusses differences among the three sets of figures.

Copper produced from domestic ores, as reported by mines, smelters, and refineries, 1945–49, in short tons

Year	Mine	Smelter	Refinery
1945	772,894	782,726	[illegible]
1946	608,737	599,656	[illegible]
1947	847,563	863,872	[illegible]
1948	834,813	842,477	[illegible]
1949	752,750	757,931	[illegible]

PRIMARY COPPER

Mine Production.—The figures for mine production are tabulated from reports supplied by all domestic mines that produce copper. These data are classified geographically, by metallurgical methods, and by types of ore. Tables presenting the information in detail are to be found in the State chapters of this volume.

As usual, Arizona led all other States by a wide margin in production in 1949, supplying nearly 48 percent of the total for the United States, followed by Utah, with 26 percent. Arizona's output comes from a number of important copper-producing districts and mines, whereas Utah's is predominantly from one mine, the largest copper producer in the United States. Production from Montana, New Mexico, Nevada, and Michigan, ranking next in importance as copper producers in 1949, made up 23 percent of the total. These six States produced 96 percent of the United States total in 1949 and 97 percent in 1948.

Classification of production by mining methods shows that approximately 70 percent of the total copper and 78 percent of the copper ore came from open pits in 1949. Most of the domestic copper ore was treated by flotation at or very near the mine of origin, and the resulting concentrates were shipped for smelting. Some copper ores were direct-smelted either because of their high grade or because of their fluxing qualities.

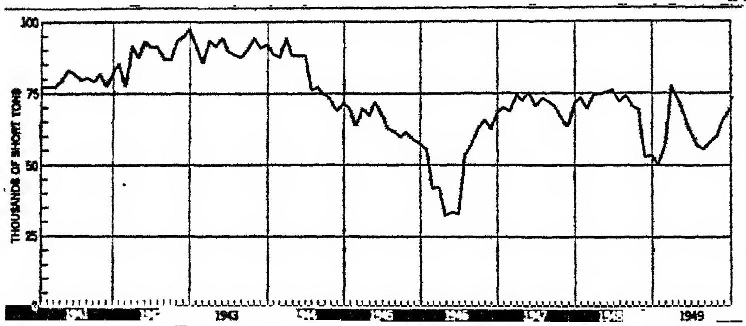

FIGURE 2.—Mine production of recoverable copper in the United States, 1941–49, by months, in short tons.

Mine production of recoverable copper in the United States, in 1949, by months [1]

Month	Short tons	Month	Short tons
January	50,002	August	55,898
February	56,410	September	58,111
March	77,912	October	60,515
April	72,843	November	66,044
May	67,412	December	69,734
June	61,254		
July	56,615	Total	752,750

[1] Monthly figures adjusted to final annual mine production total.

Mine production of recoverable copper in the United States, 1939–49, with production of maximum year, and cumulative production from earliest record to end of 1949, by States, in short tons

[1] For Missouri and States east of the Mississippi, maximum since 1905.
[2] Small quantity for Wisconsin included with Missouri.
[3] Data not available.
[4] The 1908 volume of Mineral Resources credits this figure to Massachusetts and New Hampshire; the 1909 volume credits it to New Hampshire alone.
[5] Bureau of Mines not at liberty to publish figure.
[6] Tennessee includes other States indicated by footnote 6; Bureau of Mines not at liberty to publish separate figures.
[7] Less than 1 ton.
[8] For States other than Michigan, figures represent largely smelter output. Excludes small quantity, not separable, for Wisconsin shown with Missouri.
[9] Largely smelter production for States east of the Mississippi except Michigan.

Mine production of copper in the principal districts [1] of the United States, 1940–44 (average) and 1945–49, in terms of recoverable copper, in short tons

20	Elizabeth	Orange County	Vermont	Vermont Copper Co	Copper ore.
21	Quincy	Lake Superior	Michigan	Quincy Mining Co	Copper-ore tailings.
22	Bonney-Miser's Chest	Lordsburg	New Mexico	Banner Mining Co	Copper ore.
23	Champion	Lake Superior	Michigan	Copper Range Co	Do.
24	Treasury Tunnel-Black Bear	Upper San Miguel	Colorado	Idarado Mining Co	Zinc-lead-copper ore.
25	United States & Lark	West Mountain (Bingham)	Utah	U. S. Smelting, Refining & Mining Co	Zinc-lead, gold-silver, silver ores.

The first 5 mines in the foregoing table produced 67 percent of the United States total, 10 produced 84 percent, and the entire 25 furnished 98 percent.

Quantity and Estimated Recoverable Content of Copper-Bearing Ores.—The following tables list the quantity and estimated recoverable copper content of the ore produced by mines in the United States in 1948 and 1949. Of the total copper produced from copper ores in the United States during 1949 (1948 data in parentheses), 93 (91) percent was obtained from ores concentrated before smelting, 3 (4) percent from direct-smelting ores, and 4 (5) percent from ore treated by straight leaching.

Copper ore, old tailings, etc., sold or treated in the United States in 1948–49, with copper, gold, and silver content in terms of recoverable metals

State	Ore, old tailings, etc., sold or treated (short tons)	Copper produced		Gold produced (fine ounces)	Silver produced (fine ounces)	Value of gold and silver per ton of ore

[1] Excludes copper recovered from precipitates as follows: 1948: Arizona, 16,874,713 pounds; California, 52,000 pounds; Montana, 5,503,688 pounds; Nevada, 2,055,200 pounds; New Mexico, 38,937,830 pounds; Utah, 15,658,743 pounds. 1949: Arizona, 19,923,626 pounds; California, 60,100 pounds; Montana, 4,419,019 pounds; Nevada, 1,038,400 pounds; New Mexico, 30,789,314 pounds; Utah, 15,822,418 pounds.

[2] Includes ore from Washington classed as zinc-copper ore and copper, gold and silver recovered therefrom.

[3] Copper from magnetite-pyrite-chalcopyrite ore included with that from copper ore.

Close agreement between the output as reported by smelters and the recoverable quantity as reported by mines indicates that estimated recoverable tenor is close to actual recovery. Classification of some of the complex western ores is difficult and more or less abitrary. "Copper ores" include not only all those that contain 2.5 percent or more recoverable copper but also those that contain less than this percentage if they are valuable chiefly for copper, notably the "porphyry ores." Mines report considerable copper from ores mined primarily for other products. These include siliceous gold and silver ores, lead and zinc ores, and pyritic ores.

Copper ore, old tailings, etc., concentrated in the United States in 1948–49, with content in terms of recoverable copper

[1] Includes old tailings, etc.
[2] Includes ore from Washington classed as zinc-copper ore.

Smelter Production.—The recovery of copper by smelters in the United States from ores of domestic origin totaled 757,931 short tons in 1949, a 10-percent decrease from the total of 842,477 tons for 1948. Such output constituted 51 percent of the world production during 1925–29 but dropped sharply in the succeeding years until 1934, when it was only 17 percent. From 1936 to 1940 it fluctuated between 25 and 33 percent, in 1942–44 it was slightly above 35 percent, and in 1945–49 it ranged from 29 to 35 percent.

The figures for smelter production are based upon returns from all smelters handling copper-bearing materials produced in the United States. For Michigan the sum of furnace-refined copper and copper cast into anodes for electrolytic refining is included. The figures for blister copper represent the fine-copper content. Some casting and electrolytic copper produced direct from ore or matte is included in the smelter production as well as in the refinery output. Metallic and cement copper recovered by leaching is included in smelter production.

The quantity, in pounds, of copper produced by smelters in the United States and its value are shown by years for 1845–1930 in Mineral Resources of the United States, 1930, part I (p. 703).

Copper produced (smelter output) in the United States, 1940–44 (average) and 1945–49, and total, 1845–1949

Year	Short tons	Value [1]
1940–44 (average)	1,011,893	$236,988,000
1945	782,726	184,723,000
1946	599,656	172,701,000
1947	862,872	360,680,000
1948	842,477	365,635,000
1949	757,931	298,625,000
Total, 1845–1949	35,494,521	10,613,874,000

[1] Excludes bonus payments of Office of Metals Reserve; Premium Price Plan in effect Feb. 1, 1942, to June 30, 1947.

Refinery Production.—The refinery output of copper in the United States in 1949 was made by 12 plants; 8 of these employed the electrolytic method only, 2 the furnace process on Lake Superior copper, 1 the furnace process on western ores, and 1 both the electrolytic and the furnace methods.

Five large electrolytic refineries are on the Atlantic seaboard, three Lake refineries on the Great Lakes, and three electrolytic refineries west of the Great Lakes—one at Great Falls, Mont.; one at Tacoma, Wash.; and one at El Paso, Tex. In 1942 fire-refined copper was produced for the first time at the Hurley, N. Mex., plant of the Kennecott Copper Corp., and virtually all of the plant output was treated by this method in 1949. The El Paso plant of the Phelps Dodge Refining Corp. produced fire-refined copper in addition to the electrolytic grade. Of the plants specified above, the Lake refinery of the Copper Range Co. has been idle since October 9, 1945. That of the Quincy Mining Co., idle since 1933, was reopened in the final quarter of 1948 and continued to produce through 1949. As a result of a strike at the Carteret operation of the U. S. Metals Refining Co., the refinery was idle from June 30 to October 28.

In addition to the plants in the preceding paragraph, but included in the 12 active refineries noted, is the plant at Inspiration, Ariz., which is equipped to make electrolytically refined copper direct from the liquors obtained from leaching ore. Usually all of this copper is shipped as cathodes to other refineries, where it is melted and cast into merchant shapes; but in 1946 more than one-third went directly to consuming plants. The latter practice was continued in 1947 and 1948, but on a considerably reduced scale, and virtually ceased in 1949.

Primary and secondary copper produced by primary refineries in the United States and imported, 1940–44 (average) and 1945–49, in short tons

	1940–44 (average)	1945	1946	1947	1948	1949

[1] The separation of refined copper into metal of domestic and foreign origin is only approximate, as accurate separation at this stage of manufacture is not possible.
[2] Some copper from Michigan is electrolytically refined at eastern refineries and is included as electrolytic copper.
[3] Data include copper imported for immediate consumption plus material entering country under bond.
[4] Revised figure.
[5] Includes some secondary Lake copper.
[6] Copper from scrap at Lake refineries included under "casting" copper in 1945–49.

The 13 plants indicated constitute what commonly are termed "regular refineries." Of these plants, eight employ the electrolytic process, four the furnace process, and one both methods. The electrolytic plants, exclusive of the one at Inspiration, have a rated capacity of 1,518,000 tons of refined copper a year. They produced at the rate of 68 percent of capacity in 1949.

The accompanying tables show the production of refined copper at regular refining plants, classified according to source, grade, and form in which cast.

Copper cast in forms at primary refineries in the United States, 1947–49

Form	1947		1948		1949	
	Short tons	Percent	Short tons	Percent	Short tons	Percent
Wire bars	885,000	62	783,000	58	665,000	59
Cathodes	87,000	6	76,000	5	128,000	11
Ingots and ingot bars	99,000	7	148,000	11	117,000	10
Billets	160,000	11	187,000	14	108,000	10
Cakes	178,000	13	134,000	10	106,000	9
Other forms	20,000	1	25,000	2	16,000	1
Total	1,429,000	100	1,353,000	100	1,140,000	100

In addition to the regular refineries, many plants throughout the country operate on scrap exclusively, producing metallic copper and a variety of alloys. The output of these plants is not included in the statements of refined-copper production in the preceding tables but is included in the following statement on secondary-copper production.

Copper Sulfate.—The production of hydrous copper sulfate or bluestone by copper refineries in the United States was 19,400 short tons having a copper content of 4,842 tons in 1949 compared with 24,500 tons containing 6,132 tons in 1948. The output of copper sulfate by plants other than the regular primary refineries totaled 59,600 tons with a reported content of 14,907 tons in 1949 compared with 72,200 tons containing 18,054 tons of copper in 1948. Producers held 11,800 tons of copper sulfate at the beginning of 1949, total production was 79,000 tons, and shipments amounted to 84,400 tons. Some small purchases were made by producers during the year, and producers used a quantity equivalent to 0.4 percent of shipments. Inventories at the year end were 6,400 tons.

SECONDARY COPPER

Copper recovered from copper scrap, copper-alloy scrap, and other copper-bearing scrap materials, as metal, as copper alloys without separation of the copper, or as copper compounds is known as secondary copper. Quantities are reported in terms of copper content. Secondary copper is produced from new and from old scrap. "New scrap" is defined as refuse produced during manufacture of articles for ultimate consumption, including defective finished or semifinished articles that must be reworked. Typical examples of new scrap are defective castings, clippings, punchings, turnings, borings, skimmings, drosses, and slag. "Old scrap" consists of metal articles that have been discarded after serving a useful purpose. Such articles may be worn out, obsolete, or damaged. Typical examples are discarded trolley wire, fired cartridge cases, used pipe, and lithographers' plates.

The following table summarizes the production of secondary copper during 1940–49. Detailed information appears in the Secondary Metals—Nonferrous chapter of this volume.

Secondary copper produced in the United States, 1940–44 (average) and 1945–49, in short tons

	1940–44 (average)	1945	1946	1947	1948	1949
Copper recovered as unalloyed copper	132,275	112,856	136,909	303,092	284,026	250,089
Copper recovered in alloys [1]	712,362	893,660	666,637	658,649	688,762	463,054
Total secondary copper	844,637	1,006,516	803,546	961,741	972,788	713,143
From new scrap	433,049	509,421	397,093	458,365	467,324	329,595
From old scrap	411,588	497,095	406,453	503,376	505,464	383,548
Percentage equivalent of domestic mine output	85	130	132	113	117	95

[1] Includes copper in chemicals, as follows: 1940–44 (average), 12,613; 1945, 18,666; 1946, 19,192; 1947, 18,838; 1948, 17,612; 1949, 14,840.

CONSUMPTION

The following table gives figures on apparent consumption of copper in the United States; data for a long period are available on this basis. In estimating apparent consumption, it has been assumed that copper used in manufacturing primary fabrications of copper is consumed. The method of calculating the quantity of copper available for consumption is shown in the accompanying table. It should be noted that exports and stocks include some refined secondary copper that cannot be determined separately and also that actual consumption of new copper would differ from the figures shown in the table by changes in consumers' stocks. Actual consumption of new copper had been at virtually constant rates, at peacetime peak levels, in the postwar period until 1949, when it dropped 12 percent. The apparent consumption calculation is distorted in 1947 and 1948 by the fact that during this period unusual quantities of copper were imported in the form of scrap and reexported in refined form. Because refined exports cannot be broken down to show new and old copper, deductions were made from apparent consumption without making corresponding additions to supply. The drop in 1949, thus, was probably somewhat larger than indicated by the accompanying table.

New refined copper withdrawn from total year's supply on domestic account 1945–49, in short tons

	1945	1946	1947	1948	1949
Total supply of new copper	1,639,966	1,033,033	1,309,448	1,356,570	1,203,738
Stock at beginning of year	81,000	130,000	96,000	60,000	67,000
Total available supply	1,720,966	1,163,033	1,405,448	1,416,570	1,270,738
Copper exported [1]	48,563	52,629	147,642	142,598	137,827
Stock at end of year	130,000	96,000	60,000	67,000	61,000
Total	178,563	148,629	207,642	209,598	198,827
Withdrawn on domestic account [2]	1,415,000	1,391,000	1,286,000	[3] 1,214,000	[3] 1,072,000

[1] Includes refined copper in ingots, bars, or other forms.
[2] Adjusted for Office of Metals Reserve stock changes; OMR stocks consigned to National Stockpile late in 1948.
Includes copper delivered by industry to the National Stockpile.

The Bureau of Mines began to compile figures on actual consumption of copper in 1945. Details for 1947 to 1949, inclusive, are shown in the accompanying table. Unlike the foregoing table, which attempts to eliminate all but new copper from measurement, the following one does not distinguish between new and old copper. It covers copper consumed in refined form.

The heavy consumption of wire bars in the 3 years is noteworthy. Actual consumption of refined copper declined 17 percent, a greater drop than is shown by data on apparent consumption of new metal.

Refined copper consumed in 1947–49, by classes of consumers, in short tons

Class of consumer						Other	Total
1947:							
Wire mills	2,550	757,529	17,633			52	777,764

STOCKS

Over-all industry stocks rose in 1949 against the trend since the end of 1945. The following table gives domestic stocks of copper as reported by primary smelting and refining plants. Stocks of blister and anode copper in transit from smelters to refineries are included with blister copper.

Stocks of copper at primary smelting and refining plants in the United States at end of year, 1945–49, in short tons

Year	Refined copper	Blister and materials in process of refining [1]	Year	Refined copper	Blister and materials in process of refining [1]
1945	130,000	331,000	1948	67,000	182,000
1946	95,000	254,000	1949	61,000	262,000
1947	60,000	212,000			

[1] Includes copper in transit from smelters in the United States to refineries therein.

Producers' (smelters and refineries) inventories of crude and refined copper at the end of 1949 were 29 percent above those in 1948 and exceeded 1947 by 18 percent. Only 19 percent of the 1949 total was in the form of refined copper, the remainder being in smelter shapes at smelters in transit to refineries, and blister and materials in process of refining at refineries.

Dissipation of stocks of copper in the hands of the Office of Metals Reserve was completed in 1948, either by disposal to industry or by absorption into the National Stockpile.

Fabricators' stocks of refined metal (including in-process copper and primary fabricated shapes), according to the United States Copper Association, were 354,992 tons at the end of 1949, or 6 percent less than at the beginning of the year, marking a continuation of the drop from the 423,432 tons at the end of 1947. Working stocks were 285,298 tons, or close to the tonnages so designated for the previous 3 years. After accounting for unfilled sales of metal, the deficiencies of stocks in relation to unfilled orders fell 114,140 tons to 36,920 tons at the end of 1949. The latter tonnage marked the smallest deficiency in the period during which stocks have been inadequate to fill orders, beginning in 1941; at the end of 1941 stocks failed by 304,675 tons to cover booked orders.

Figures compiled by the Copper Institute show that domestic stocks of refined copper increased from 96,080 tons at the end of 1948 to 116,027 tons at the end of 1949. Inventory data of the Bureau of Mines and the Copper Institute always vary owing to somewhat different bases. Before 1947, a primary reason was that the Copper Institute coverage was limited to duty-free copper. The inclusion by the Copper Institute of all copper after January 1, 1947, reduced the differences chiefly to variations in individual interpretation. In the Bureau of Mines classification, cathodes to be used chiefly for melting and casting into shapes are considered stocks in process and not refined stocks.

Stocks of copper in fabricators' hands at end of year, 1945–49, in short tons

	Stocks of refined copper [1]	Unfilled purchases of refined copper from producers	Working stocks	Unfilled sales to customers	Excess stocks over orders booked
1945	375,618	44,100	268,490	362,436	−211,208
1946	411,013	59,421	286,418	526,648	−342,632
1947	423,432	103,765	293,859	338,260	−104,922
1948	379,346	81,496	295,958	315,944	−151,060
1949	354,992	82,793	285,298	189,407	−36,920

[1] Includes in-process metal and primary fabricated shapes. Also includes small quantities of refined copper held at refineries for fabricators' account.

PRICES

Reports to the Bureau of Mines from copper-selling agencies indicate that 1,129,000 short tons of copper were delivered to domestic and foreign purchasers in 1949 at an average price (f. o. b. refinery) of 19.7 cents a pound—a drop of 9 percent from the 21.7 cents in 1948 but 43 percent above the annual average for 1942–47. The averages for 1942–47 exclude bonuses paid for overquota outputs of individual

mines, which were first applicable to February 1942 tonnages; the Premium Price Plan ended June 30, 1947. The history of the Premium Price Plan is given briefly in Minerals Yearbook, 1947 (pp. 466–468), and at greater length in Bureau of Mines Information Circular 7536.

Average monthly quoted prices of electrolytic copper for domestic and export shipments, f. o. b. refineries, in the United States, 1948–49, in cents per pound

Month	Domestic f. o. b. refinery [1]	Domestic f. o. b. refinery [2]	Export f. o. b. refinery [2]	Domestic f. o. b. refinery [1]	Domestic f. o. b. refinery [2]	Export f. o. b. refinery [2]

[1] As reported by American Metal Market.
[2] As reported by E&MJ Metal and Mineral Markets.

The average quoted price for electrolytic copper, f. o. b. refinery, was 23.2 cents a pound at the beginning of the year. Demand collapsed at the end of the first quarter, following the beginning of the general industrial reaction at the time; the price dropped to 22.95 at the end of March, lagging behind initial declines for lead and zinc. Subsequent falls carried the copper price to 15.7 cents on June 17. An upward movement began with the rise to 16.525 cents on July 6; as a result of additional gains the price was 18.2 cents in early November and remained there beyond the end of the year. The average price for the year—19.202 cents—was 13 percent less than that in 1948—22.038 cents. The average quoted price for export copper, f. o. b. refinery, was 19.421 cents in 1949 and 22.348 in 1948. The export price ranged from 0.081 cent a pound higher than the domestic price in July to 0.256 in May and averaged 0.219 for the year compared with 0.310 in 1948.

London Price.—The official price of the British Ministry of Supply for electrolytic copper, delivered buyers' plants, was £140 per long ton (25.2 cents a pound) from October 1, 1948, through May 15, 1949.

On May 16 the price began a descent during which it reached £104 on July 12; on July 13 it rebounded to £107 10s. On September 22, after devaluation of the pound sterling, the price was returned to £140 a ton (then equivalent to only 17.5 cents a pound) and on November 4 rose to £153 (19.1 cents a pound). Statutory maximum prices for copper, lead, and zinc were revoked as of November 15, 1949.

FOREIGN TRADE [2]

Before World War II the United States produced more copper than domestic industry could utilize and consequently, had a surplus available for exportation. United States smelting and refining plants, moreover, had capacity that exceeded domestic production, and this excess capacity was used to smelt and refine imported copper under bond for reexportation in refined or in manufactured forms. The excise tax placed on copper June 21, 1932, was effective chiefly in preventing foreign copper from invading domestic consumption channels. Copper smelted, refined, and fabricated under bond was not subject to the 4-cent tax. The exportable surplus no longer held when the war program called for all copper available from domestic and foreign sources and when, despite the addition of foreign supplies, the filling of most civilian requirements had to be postponed. The Government became the importing agent in the war, and the excise tax thus was ineffective. In the postwar period, demand continued far above the prewar level as postponed civilian demands were filled and the general industrial level continued high. The Government discontinued importing copper at the war's end. To encourage imports so that expanded peacetime demand could be filled the excise tax was suspended, effective April 30, 1947–June 30, 1950. Early in 1949 the tariff concession on copper, contained in the General Agreement on Tariffs and Trade (Geneva conference, October 1947), became effective under suspension. This concession reduced the excise tax to 2 cents. If the tax suspension terminates on June 30, 1950, as provided by legislation in effect in 1949, the tax when reimposed will be 2 instead of 4 cents a pound, as before the war.

IMPORTS

Total imports of unmanufactured copper rose 9 percent in 1949 and established a new peacetime record for the second successive year. Entries of refined copper, the most important class, gained 11 percent and of concentrates 34 percent, whereas the unrefined class (second in importance) dropped 2 percent; the other classes are relatively small. The increase in refined imports came largely from Canada and Peru because Chile, the chief source of this type, failed by nearly 20,000 tons to equal its record for 1948. Receipts of concentrates rose chiefly because of larger entries from Canada, Chile, Cyprus, the Union of South Africa, and Mexico. Much smaller receipts of unrefined copper from Chile and Peru slightly more than offset the larger quantities from Yugoslavia, Northern Rhodesia, and Mexico and the new imports from Turkey, resulting in the small decline noted.

[2] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Copper (unmanufactured) imported into the United States, 1940–44 (average) and 1945–49 [1]

[U. S. Department of Commerce]

Year	Short tons	Year	Short tons
1940–44 (average)	608,617	1947	[2] 413,890

[1] Changes for table in Minerals Yearbook, 1947, p. 470, are as follows for 1946: Ore imported from Chile, 1,346 tons; Mexico, 3,384 tons; other countries, 163 tons; total, 4,895 tons. Concentrates, Chile, 2,962 tons; Canada, 9,366 tons; other countries, 118 tons; total, 41,844 tons. Unrefined, Mexico, 56,024 tons; total, 193,387 tons.
[2] Data include copper imported for immediate consumption plus material entering the country under bond.
[3] Revised figure.
[4] Tonnages credited to Southern Rhodesia by the U. S. Department of Commerce have been added to Northern Rhodesia.
[5] Some copper in "ore" and "other" from Republic of the Philippines is not separately classified and is included with "concentrates."

EXPORTS

Most of the copper exported from the United States is in advanced forms of manufacture, in which the copper content is not determined, and in the form of refined copper. Shipments in refined form dropped 3 percent in 1949. Thirteen countries received quantities exceeding 1,400 tons, the United Kingdom being the destination of 26,236 tons, France 23,948, India 20,514, Italy 19,914, the Netherlands 11,611, Germany 10,600, and Switzerland 9,374 tons. The quantity exported to the United Kingdom was sharply contracted from 1948, whereas all other countries mentioned, except Switzerland, had noteworthy gains that, however, were insufficient to counterbalance the drop in shipments to the United Kingdom.

Of the other classes exported, rods rose 56 percent and old and scrap advanced to several times the small quantity in 1948. All other classes covered by the accompanying table declined in 1949.

Copper exported from the United States, 1940–44 (average) and 1945–49

WORLD REVIEW

In the leading copper-producing countries of the world in 1949, output expanded in Northern Rhodesia and Canada and dropped in the United States, Chile, and the Belgian Congo. The decreases approximately counterbalanced the gains, and the world total differed little in 1949 from that in 1948. The indications are that output in the U. S. S. R. rose in 1949, but data for this country continue unsatisfactory.

World mine production of copper, 1943–49, in metric tons

[1] Copper content of blister produced.
[2] Smelter output from domestic and foreign ores, exclusive of scrap. Production from domestic ores only, exclusive of scrap, was as follows: 1943, 891,492; 1944, 910,245; 1945, 710,073; 1946, 543,996; 1947, 782,780 1948, 764,278; 1949, 687,580. The diversion during the war of Belgian Congo matte from its previous destination, Belgium, for resmelting in the United States resulted in some duplication. The movement ended in 1945.
[3] United States imports.
[4] Figures represent blister copper only. Belgium reports a large output of refined copper which is not included above as it is believed produced principally from crude copper from Belgian Congo and would therefore duplicate output reported under the latter country.
[5] Data not available; estimate by authors of chapter included in total.
[6] Exclusive of material from scrap.
[7] Approximate production.
[8] Includes scrap.
[9] American and British zones only.
[10] Output from U. S. S. R. in Asia included with U. S. S. R. in Europe.
[11] Data represent areas designated as Free China during the period of Japanese occupation.
[12] Preliminary data for fiscal year ended March 31 of year following that stated.

Belgian Congo.—The drop in output in Belgian Congo is explained chiefly by the unusually small precipitation during the rainy season, leading to inadequate water supplies for the Francqui power plant at Cornet Falls. The reserve steam plants at Jadotville and Lubum-

bashi were placed in service; but insufficient coal deliveries, impeded by inadequate transportation facilities, made it impossible to operate the reserve plants at full capacity. Power shortages, it is believed, will end permanently when the new Bia power plant is started and attains full operation, expected to take place in early 1950. The mines being worked by the Union Minière du Haut Katanga, chief of which were Kipushi (Prince Leopold), Musonoie, Kolwezi, Luishia, Kamoto, and Kalabi, produced ore containing copper principally. Expansion of the Kolwezi and Kipushi concentrators and of the Jadotville-Shituru electrolytic plant proceeded during the year. An exhaustive description of the Lubumbashi smelter was made available in 1949.[3]

Exports of Belgian Congo copper leave through the ports of Matadi, Belgian Congo; Lobito, Angola; and Beira, Mozambique. Exports, by kinds and destinations, in the first 9 months of 1949 were as follows: [4]

	Metric tons
Shituru cathodes:	
Belgium	220
Lobito depot	388
Total	608
Wire bars (99 percent):	
Beira depot	21,754
Belgium	18,061
Denmark	508

According to another report by Murdock, a published report on ore reserves placed copper (metal) reserves in the Congo at more than 10,000,000 tons at the end of 1945. He stated also that Professor Robert, in his 1946 edition of Le Congo physique, placed reserves at 9 to 12,000,000 tons of copper in ore averaging 6 percent.

Canada.—Both mine and refinery production of copper rose in 1949, marking extensions of the annual gains since the recent low levels of 1946. Mine output was the largest since 1944 and refinery output the greatest since 1945.

Copper produced (mine output) in Canada, 1945–49, by Provinces, in short tons

Province	1945	1946	1947	1948	1949 (preliminary)
British Columbia	12, 876	8, 750	20, 900	21, 502	27, 377
Manitoba	20, 563	19, 251	15, 316	18, 960	17, 351
Newfoundland (not Canadian 1945–48)	--------	--------	--------	--------	3, 479
Ontario	119, 726	89, 712	113, 934	120, 383	112, 096
Quebec	51, 342	34, 999	42, 561	48, 813	68, 421
Saskatchewan	32, 950	31, 356	33, 151	31, 074	34, 894
Total	237, 457	183, 968	225, 862	240, 732	263, 618

Ontario fell from its customary place as supplier of more than half of Canada's copper from the nickel–copper ores of the Sudbury district; it produced 43 percent of the 1949 total. The inclusion of Newfoundland's output in Canadian figures for the first time in 1949 did not change Ontario's percentage share. The International Nickel Co. of Canada, Ltd., is by far the largest copper producer in Canada. Production of copper, nonetheless, is determined in large part by conditions in the nickel market, because the latter metal is the principal value in the ore. Reserves proved during the year exceeded the tonnage mined and were 251,805,000 short tons at the end of 1949 compared with 246,177,000 tons at the beginning of the year. The combined nickel–copper content was 7,630,000 and 7,503,000 tons, respectively. In 1949, 9,984,891 tons of ore were mined compared with 10,866,862 in 1948 and 10,406,644 in 1947. The company sold 110,538 tons of copper in 1949 compared with 109,565 in 1948. In the same periods sales of nickel in all forms

aggregated 104,646 and 120,049 tons, respectively. The company is attempting to prepare the underground mines for greater production to compensate for the approaching completion of work at the low-grade Frood-Stobie open pits. A new concentrator is under construction at the mine site of the Creighton mine and is scheduled for completion by 1951. The concentrator will have a capacity of 6,000 tons a day and will supply the concentrate by pipeline to Copper Cliff, approximately 7½ miles. The Falconbridge Nickel Mines, Ltd. —the other important producer in Ontario—hoisted 921,916 tons at the Falconbridge mine in 1949 compared with 821,284 in 1948. Development ore at the McKim mine was 15,896 tons compared with none. Mine, smelter, and refinery outputs were at new peaks; inventories of matte and refined copper increased. Developed ore reserves at the Falconbridge and McKim mines aggregated 8,592,000 tons, averaging 1.62 percent nickel and 0.85 percent copper, and indicated reserves in outside holdings totaled 6,199,000 tons averaging 1.86 and 1.01 percent, respectively.

Quebec is ordinarily Canada's second-largest copper-producing Province; it supplied most of Canada's increase in 1949. Noranda Mines, Ltd., is an outstanding producer. A total of 1,257,202 tons of ore was hoisted at the Horne mine; 794,152 tons were milled and 601,851 tons of ore and concentrates smelted. The smelter also treated 454,929 tons of custom material. Copper output for the Horne mine was 25,948 tons out of a total smelter output of 68,502 tons of new copper. In addition, the Horne mine produced 185,418 ounces of gold and 524,315 ounces of silver. Developed ore reserves above the 2,975-foot level were 17,507,000 tons, averaging 2.24 percent copper and 0.187 ounce of gold per ton, of which 4,290,000 tons averaged 7.13 percent and 0.161 ounce, and 13,217,000 tons averaged 0.66 percent and 0.196 ounce. Production was begun at the newly developed East Sullivan mine at the close of 1948 and was a factor in the larger copper output of Quebec in 1949. The copper is custom-reduced by Noranda. The property of the Quemont Mining Corp., Ltd., which adjoins the Horne mine and in which Noranda has a substantial interest, began to produce in 1949; the mill was started on June 20. Metals contained in shipments were 5,643 tons of copper, 42,081 ounces of gold, 155,973 ounces of silver, and 198 tons of zinc. All copper-concentrate and cyanide-plant base bullion were delivered to the Noranda smelter. In an address to stockholders in April 1949, the president said that the company had an agreement which permitted sale of 90 percent of its refined copper to the United States stockpile until March 31, 1953, on a satisfactory pricing basis. Ore reserves at the end of 1949 were reported as 9,229,500 tons, averaging 1.50 percent copper, 0.17 ounce of gold and 0.95 ounce of silver to the ton, and 2.78 percent zinc. A total of 292,235 tons of ore, containing 2.92 percent copper, 7.50 percent zinc, and 0.031 ounce of gold and 2.61 ounces of silver per ton, was milled by the Normetal Mining Corp., Ltd. Recoverable metals totaled 7,586 tons of copper, 4,725 ounces of gold, 434,199 ounces of silver, and 17,696 tons of zinc. Copper concentrate is smelted at Noranda and zinc concentrate shipped to the United States. Estimated reserves were 1,452,800 tons, containing 3.53 percent copper and 7.71 percent zinc. Ore milled by the Waite Amulet Mines, Ltd. (controlled by

Noranda), at the Waite and Amulet Dufault mines totaled 453,174 tons, from which were recovered 16,749 tons of copper, 20,821 tons of zinc, 8,857 ounces of gold, and 426,666 ounces of silver. The development of additional tonnages of ore and higher metal prices prevented anticipated exhaustion of shafts "F" and "C" of the Waite mine. Mining of a new lower-grade "C" ore body will begin in the summer of 1950. Disclosure by diamond drilling of a massive sulfide ore body 3,000 feet east of the old Waite mine led to sinking of a shaft, the "East Waite." A year will be required to complete the necessary work to determine the size and grade of the new ore body. Ore reserves at Waite were 48,000 tons and at Amulet Dufault 1,022,972 tons of ore averaging 5.57 percent copper and 4.02 percent zinc and 79,212 tons averaging 1.8 percent copper and 6.5 percent zinc. The Canadian Copper Refiners, Ltd. (controlled by Noranda), produced 111,100 tons of refined copper in 1949 compared with 95,400 tons in 1948. Approximately 1 million dollars was spent, chiefly in connection with the production of vertically cast copper cake and billets.

Copper produced in Saskatchewan and Manitoba comes almost entirely from the Flin Flon mine of the Hudson Bay Mining & Smelting Co., Ltd., and the Sherridon operation of Sherritt Gordon Mines, Ltd. At the Hudson Bay mine 1,885,107 tons were mined, of which 1,853,476 tons were milled and the remainder was direct-smelting ore. The copper smelter treated 359,026 tons of Hudson Bay concentrates and ores and 60,958 tons of custom concentrates. Company material shipped to the refinery contained 42,633 tons of copper, 121,286 ounces of gold, 1,868,507 ounces of silver, and 143,615 pounds of selenium.[5] Estimated ore reserves, as of January 1, 1950, were 20,157,000 tons, averaging 2.04 percent copper, 4.34 percent zinc, and 0.084 ounce of gold and 1.14 ounces of silver per ton. At Sherridon 432,524 tons of ore were mined and milled, and 9,480 tons of copper, 5,247 ounces of gold, 172,317 ounces of silver, and 10,128 tons of zinc concentrate produced—only slightly below the performance in 1948. Year-end reserves were 396,400 tons, averaging 2.44 percent copper, 1.88 percent zinc, and 0.019 ounce of gold, and 0.58 ounce of silver per ton. No new reserves were developed; but the mining of some marginal ore, permitted by high metal prices, caused reserves to be reduced less than the quantity mined. Life of the mine may extend into early 1951. At Lynn Lake, mine-development and pilot-plant operations were pushed. Continuation of the 1949 program in 1950 is contemplated, with the prospect that the foundations for the permanent plant at the "El" shaft will be prepared. The economics of moving the town of Sherridon to Lynn Lake will be investigated. An additional 2,000,000 tons of ore were proved in 1949, and reserves at the end of the year were 10,365,000 tons, averaging 1.443 percent nickel and 0.681 percent copper and 153,000 tons containing 1.113 percent copper, 2.491 percent zinc, and 0.016 ounce of gold per ton.

Chief producers in British Columbia are the Granby Consolidated Mining, Smelting & Power Co., Ltd., and the Britannia Mining & Smelting Co., Ltd. Granby celebrated 50 years of mining in 1949; aggregate recovery of copper in the 50 years was 685,030 tons from 58,860,783 tons of ore.

[5] Selenium reported as contained in material shipped in 1948, Minerals Yearbook, 1948, p. 459, was erroneously stated as 138,507 ounces instead of pounds.

Exports of ingots, bars, and billets from Canada in 1949 as compared with 1948 were as follows, by countries of destination, in short tons:

Destination:	1948	1949
United Kingdom	63, 493	59, 491
United States	18, 085	50, 212
France	14, 098	7, 403
India	2, 936	5, 741
Switzerland	4, 120	1, 847
Brazil	--------	790
Netherlands	2, 497	756
Czechoslovakia	6, 411	392
Poland	2, 295	--------
Other countries	2, 234	528
Total	116, 169	127, 160

Exports of copper in ore totaled 37,057 tons, of which 29,650 went to the United States, 6,495 to Norway, 800 to the United Kingdom, and 112 to Belgium, compared with 28,555, 22,624, 5,346, 585, and no tons, respectively, in 1948. In addition, 31,529 tons of rods, strips, sheet, and tubing and 3,514 of scrap were shipped from the country compared with 28,639 and 5,236 tons, respectively, in 1948.

Chile.—Mine and smelter production of Chilean copper declined in 1949 because of lower outputs at all of the three large copper-producing mines. Martial law in effect [6] in mining zones was suspended January 27, 1949. It was reimposed, however, August 22, owing to disorders in Santiago and in the coal fields, attributed to Communist activities; it remained in effect at the end of the year.

Continuation of the conditions of inadequate supply of skilled underground labor for 3 years at the Braden mine, Kennecott Copper Corp., caused mine development to lag behind production requirements. Thus a large-scale development program was necessary in 1949 to prepare the mine for future production. At the Braden mine, 7,914,000 short tons, assaying 2.14 percent copper, were mined and milled. Smelter output was 139,592 tons of copper, compared with 164,252 tons in 1948.

The Chuquicamata mine of the Chile Exploration Co., a subsidiary of the Anaconda Copper Mining Co., produced 193,001 short tons of copper in 1949 compared with 229,285 tons in 1948, a continuation of the decrease from 243,565 tons in 1947. Ore treated averaged 1.59 percent copper in 1949. Construction of the new plant for treatment of sulfide ores proceeded continuously on the schedule of completing the plant and bringing it into operation during the first half of 1952.

At the Andes mine 54,421 tons of ore were produced, a 27-percent drop from 74,529 tons in 1948. The company is now [7] mining sulfide ores only and is producing 3,500 to 4,000 metric (3,900–4,400 short) tons a month, compared with 5,000 to 5,500 (5,500–6,100) previously. Sulfide ore reserves, it is said, will permit 15 years' operations at the current rate of depletion. Ore processed in 1949 averaged 0.968 percent copper.

The Chilean-owned small and medium-size mining industry had little activity in 1949. Construction of the Paipote national smelter, near Copiapo, was being pushed at the year's end. The Government granted subsidy during the year to high-cost, small mines.

[7] Bureau of Mines, Mineral Trade Notes: Vol. 30, No. 6, June 1950, pp. 13-15.

Exports of the chief copper classes, by countries, are shown as follows, in metric tons:

	Electrolytic	Standard (furnace refined)	Total
United States	188, 405	47, 536	235, 941
France	31, 089	4, 500	35, 589
Great Britain	16, 978	6, 934	23, 912
Italy	5, 690	11, 218	16, 908
Brazil	11, 582	388	11, 970
Poland	--------	5, 334	5, 334
Germany	4, 088	1, 193	5, 281
Netherlands	3, 022	152	3, 174
Belgium	2, 700	--------	2, 700
Algeria	2, 405	--------	2, 405
Argentina	2, 139	--------	2, 139
Switzerland	1, 930	--------	1, 930
Denmark	1, 413	277	1, 690
Spain	1, 380	--------	1, 380
Sweden	846	381	1, 227
Other countries	2, 209	--------	2, 209
Total	275, 876	77, 913	353, 789

Other copper exports from Chile, all to the United States, were 1,176 metric tons of ore, 14,021 tons of concentrates, 130 tons of precipitates, and 181 tons of cement copper.

Cyprus.—The principal producer, the Cyprus Mines Corp. operated its Mavrovouni mine throughout the year,[8] except for a 5-day fire, and produced 723,980 tons of pyrites from which the treatment plant at Xeros recovered 99,290 tons of copper concentrate averaging 18.6 percent Cu, 415,366 tons of flotation pyrites averaging 49.3 percent S, and 1,611 tons of cement copper averaging 59.2 percent Cu. A further 85,997 tons of copper pyrites was added to the stockpile. Exports included 77,820 tons of copper pyrites to Italy, 65,165 tons of copper concentrates to Germany, and 46,225 tons to the United States and 2,010 tons of cement copper (destination not given); the copper content of total copper-bearing exports was estimated at 23,558 tons. The Skouriotissa mine remained closed in 1949, but extensive investigations were made of the possibility of working the remainder of the ore body by open-cut methods. Drilling was also done at the Apliki mine, with no ore of commercial grade encountered thus far.

Finland.—Outokumpu Oy, owned by the Finnish Government and by far the largest copper producer in Finland, is said [9] to be producing 20,000 to 21,000 tons of electrolytic copper a year, all of which is believed to be oxygen-free. Originally the smelter at Harjavalta smelted concentrates to matte electrically, the matte being then converted to blister and electrolytically refined. Since 1948, the report stated, concentrates have been smelted without use of energy other than that contained in the ore. The company also has copper, brass, and bronze foundries, a rolling mill which produces plate and strip, and a tube mill.

India.—According to a recent report,[10] the Government of India is investigating possibilities of building a copper refinery in India. Increased activity in the electrical field, it is said, will cause India's

[8] The Mining Journal, Cyprus Mineral Output Booms in 1949: Vol. 234, No. 5986, May 12, 1950, p. 490.
[9] Metal Bulletin (London), No. 3450, Dec. 13, 1949, p. 16.
[10] Chemical Age (London), vol. 62, No. 1592, Jan. 14, 1950, p. 90.

consumption to rise from 35,000 to probably 60,000 tons. Present production averages only about 7,000 tons annually from the Singhbhum district, Bihar, the only productive area. Small deposits are said [11] to be numerous, however, especially in parts of Rajputana and Bihar, and investigations suggest the occurrence of copper lodes in Darjeeling, Sikkim and Kumaon Himalayas, and elsewhere.

Northern Rhodesia.—Mine and smelter production of copper in Northern Rhodesia made noteworthy gains in 1949. Inadequate rail facilities and a consequent shortage of coal, however, continued to hamper full-scale operations, though more intensive wood burning permitted an increase in over-all operations as compared with 1948. A new subsidiary with which all the copper-mining companies are associated is the Northern Rhodesia Power Corp., Ltd.,[12] which is arranging for the interconnection of the electrical power systems of the four mines and will explore the possibilities of hydroelectric power from the Kariba, Kafue, and other sources. This plan will permit economies in necessary standby equipment and in extensions to the power plants needed to meet anticipated increased demand.

Satisfactory progress was reported in extensions being made to the electrolytic refinery of the Rhodesian Copper Refineries.

A total of 3,060,100 short dry tons of ore, containing 2.35 percent copper, was mined at the Roan Antelope mine in the fiscal year ended June 30, 1949, or 6 percent more than in the preceding 12 months. Production of blister copper amounted to 62,901 short tons in 1948–49 compared with 57,968 tons in 1947–48. Ore reserves at the end of June 1949 were estimated at 92,706,087 tons, containing 3.25 percent copper.

The Rhokana Corp., Ltd., produced 122,418 (106,254 in 1947–48) short tons of copper in the year ended June 30, 1949, of which 13,734 (13,108 tons in 1948) tons were Nkana blister copper, 38,438 (28,843) Nchanga blister, and 70,246 (64,573) Nkana electrolytic copper. Ore reserves at the end of June 1949 were as follows:

	Short tons	Copper (percent)
Nkana north ore body	32, 160, 000	3. 20
Nkana south ore body	20, 165, 000	2. 78
Mindola ore body	54, 963, 600	3. 64
	107, 288, 600	3. 35

The extension program at Nchanga—to increase production to 64,000 long (72,000 short) tons of copper—was reported to have progressed satisfactorily and was expected to be completed by the end of 1950. According to the Yearbook of the American Bureau of Metal Statistics for 1949, reserves at the Nchanga mine in 1949 were 139,674,000 short tons, averaging 4.66 percent copper.

The Mufulira Copper Mines, Ltd., mined 2,973,935 short dry tons of ore, averaging 3.12 percent copper, in the year ended June 30, 1949. Blister copper output was 79,482 tons compared with 59,763 in 1947–48. Ore reserves on June 30, 1949, were 129,304,000 tons, averaging 3.85 percent copper, in the Mufulira, Chambishi, and Baluba mines. Block caving has been introduced to replace sublevel caving at the Mufulira mine and about 56 percent of the tonnage hoisted was obtained by the replacement method.

[11] The Metal Bulletin (London), Mineral Resources of India: No. 3410, July 22, 1949, p. 8.
[12] The Rhodesia Mining Review, No. 171 (new series), December 1949, p. 21.

Mining methods at Mufulira were described in the December Bulletin of the Institute of Mining and Metallurgy and later condensed.[13]

U. S. S. R.—The metal Bulletin[14] published estimates on the primary metal outputs of the Soviet Union, based on official indications and other sources. According to the estimates, output of copper in the U. S. S. R. was as follows:

	Metric tons		*Metric tons*
1944	170,000	1948	200,000
1945	160,000	1949	225,000
1946	170,000	1950 (target)	250,000
1947	185,000		

These figures are higher than other estimates available to the Bureau of Mines and incorporated in the table on world production.

United Kingdom.—Second only to the United States as a consumer of copper, the United Kingdom used 496,720 long tons in 1949 (of which 318,736 were virgin copper and 177,984 scrap), a drop of 8 percent from the 538,655 tons (of which 356,793 were virgin and 181,862 scrap) in 1948. Of the totals shown for 1949, 305,614 tons were used in unalloyed form, 180,227 as alloys (chiefly brass), and 10,879 in copper sulfate. Stocks of virgin blister and refined copper (Government and industry) in the United Kingdom totaled 129,674 tons at the end of 1949 compared with 120,721 at the year's beginning. These inventories include electrolytic (including rods), fire-refined, and blister and stocks in transit in the United Kingdom.

At the beginning of the year the price of the British Ministry of Supply was £140 a long ton (25.2 cents a pound), but it was dropped to £104 (18.7 cents) on July 12. After devaluation of the pound in September, the price rose to £140 a ton again but then was equivalent to only 17.5 cents a pound. A further increase to £153 (19.1 cents) occurred on November 4. Statutory maximum prices for copper, lead, and zinc were revoked, as of November 15, 1949.

Imports of the important classes in 1949, in long tons, were as follows:

Source:	*Electrolytic*	*Standard*	*Total*
Northern Rhodesia	36,559	112,887	149,446
Canada	53,267		53,267
United States	24,137		24,137
Chile	1,883	21,960	23,843
Belgium	21,824		21,824
Belgian Congo	17,249		17,249
Other countries	20,660	290	20,950
Total	175,579	135,137	310,716

The gross weight of copper ore imported—all but 2 tons from Canada—was 32,773 tons. Exports in 1949 were as follows:

	Long tons
Copper ingots, etc	32,109
Plates, sheets, rods, etc	14,808
Wire (including uninsulated electric wire)	31,377
Tubes	6,102
Other manufactures	5,126
Total	89,522

Feldspar

By Robert W. Metcalf

GENERAL SUMMARY

PRODUCTION of crude feldspar in 1949 declined 20 percent and sales of ground feldspar 24 percent compared with 1948 figures and were the lowest since 1944 and 1945, respectively. Total values decreased 11 percent for crude and 13 percent for ground feldspar. Factors contributing to this decline were the reduction in glass container shipments about the middle of the year, the general slackening of business activity, and increasing competition from nepheline syenite, aplite, and to some extent blast-furnace slag. Aplite production also declined, but less sharply than feldspar. Imports of Canadian crude feldspar in 1949 dropped nearly 50 percent. Although imports of unground nepheline syenite were about one-quarter less than in 1948, receipts of ground nepheline syenite more than doubled in 1949.

Salient statistics of the feldspar industry in the United States, 1940–44 (average), and 1946–49

	1940–44 (average)	1946	1947	1948	1949
Crude feldspar:					
Domestic sales:					
Long tons	316,275	508,380	459,910	460,713	369,378

Average per long ton	$4.93	$5.10	$5.26	$5.57	$6.17
Imports:					
Long tons	11,149	16,365	16,665	31,047	15,836
Value	$80,467	$127,654	$124,587	$219,785	$107,925
Average per long ton	$7.22	$7.80	$7.47	$7.08	$6.82
Ground feldspar:					
Sales by merchant mills:					
Short tons	329,395	470,180	482,799	506,463	388,707
Value	$3,565,610	$5,344,107	$5,861,141	$6,462,231	$5,608,101
Average per short ton	$10.83	$11.37	$12.14	$12.76	$14.43

Sales of crude feldspar in Arizona, Connecticut, and Georgia were higher in 1949 than in 1948. Virtually all other States reported decreased tonnages, ranging from about 2 to 20 percent or more. North Carolina continued to be the largest producing State, with 44 percent of the total output in 1949. All States reporting ground feldspar in 1949 reported losses in tonnage except Georgia. Connecticut-New Jersey, Virginia, and Arizona had moderate declines in ground feldspar sold, and the other grinding States all reported substantial decreases, including an 18-percent decline for New York and a 27-percent drop for North Carolina-Tennessee. Toward the end of 1949, however, both crude and ground feldspar experienced a considerable resurgence, and production at the end of the year was at a high level.

DOMESTIC PRODUCTION

CRUDE FELDSPAR

Production of crude feldspar in 1949 decreased 20 percent to the lowest point since 1944, and the total value decreased 11 percent compared with 1948. The average value per ton rose 11 percent to $6.17. Feldspar in 1949 was mined in 13 States, compared with 12 in 1948, Texas again reporting a small output.

Crude feldspar sold or used by producers in the United States, 1944–49

Year	Long tons	Value: Total	Value: Average	Year	Long tons	Value: Total	Value: Average
1944	327,406	$1,813,937	$5.54	1947	459,910	$2,410,940	$5.24
1945	373,054	2,021,529	5.42	1948	460,713	2,564,387	5.57
1946	508,380	2,594,099	5.10	1949	369,378	2,278,441	6.17

Undistributed [2]	43,351	276,739	59,991	404,501	50,343	347,652
Total	459,910	2,410,940	460,713	2,564,387	369,378	2,278,441

[1] Included with "Undistributed."
[2] Includes Arizona, California, Georgia, Maryland (1947), New Hampshire, New York, Texas (1947 and 1949), and Wyoming (1949).

Output of crude feldspar in Arizona and Connecticut was slightly higher than in 1948. Although relatively small in actual tonnage, production in California and Georgia made large proportional gains. All other States in 1949 showed losses in tonnage, varying from 2 or 3 percent for Colorado, Maine, and Virginia to 20 percent for North Carolina and even higher percentages for several of the other States. The largest producing State, as for many years, was North Carolina, with 44 percent of the total output, followed by Colorado with 17 percent, and Virginia and South Dakota each with 9 percent of the total.

GROUND FELDSPAR

The output of ground feldspar by merchant mills in 1949 dropped 24 percent to 336,707 short tons, the lowest figure since 1945. The total value decreased 13 percent, and the average value per ton rose 14 percent to $14.50. Ground feldspar was produced in 14 States in 1949 compared with 13 in 1948, California again reporting a small tonnage. Georgia was the only State in which more feldspar was ground in 1949

than in 1948. Shipments by Colorado mills totaled 18 percent of the total sales in 1949, compared with 16 in 1948 and 14 in 1947. Sales by North Carolina-Tennessee mills in 1949 were 41 percent of the total feldspar ground, compared with 43 percent in 1948 and 45 percent in 1947, and shipments by Maine grinding plants were about 4 percent of the total sales in each of these 3 years.

Ground feldspar sold by merchant mills [1] in the United States, 1945–49

Year	Active mills	Domestic feldspar			Canadian feldspar			Total	
		Short tons	Value		Short tons	Value		Short tons	Value
			Total	Average		Total	Average		
1945	30	372,377	$4,062,077	$10.91	9,351	$184,884	$19.77	381,728	$4,246,961

[1] Excludes potters and others who grind for consumption in their own plants.

North Carolina again was the largest grinder of feldspar, followed by Colorado, Virginia, and South Dakota. Connecticut-New Jersey, Virginia, and Arizona showed moderate decreases compared with 1948, and the other producing States reported large declines in output, ranging from 18 percent for New York to 27 percent for North Carolina-Tennessee and higher for certain other States.

[1] Excludes potters and others who grind for consumption in their own plants.
[2] Includes (number of active mills in parentheses) Arizona (1), California (1 in 1949), Georgia (1 in 1948–49), Illinois (1), New Hampshire (2 in 1947, 3 in 1948–49), New York (3), South Dakota (3 in 1947–48, 2 in 1949), and Virginia (2).

The Colorado feldspar industry and the operations of the Parkdale, Colo., flotation mill of the Consolidated Feldspar Corp. were described.[1] A study of the pegmatites and their relation to feldspar occurrence and production in Fremont County, Colo., was published.[2]

[1] Mattson, V. L., Feldspar: Mines Mag., vol. 39, No. 4, April 1949, pp. 25–26.
Pit and Quarry, vol. 42, No. 5, November 1949, p. 77.
[2] Heinrich, E. W., Pegmatites of Eight-Mile Park, Fremont County, Colo.: Am. Mineral., vol. 33, Nos. 7–8, July–August 1948, pp. 420–448; Nos. 9–10, September–October 1948, pp. 550–587; Am. Ceram. Soc. Jour., vol. 32, No. 3, Mar. 1, 1949, pp. 89–90.

The new feldspar plant of the Appalachian Minerals Co., Monticello, Ga., and methods of processing were described in detail.[3] A study of the pegmatites in Montana included data on the occurrences of feldspar in that State.[4] The pegmatites of the Spruce Pine area in North Carolina were described.[5] Mining, crushing, and milling methods used by the Feldspar Flotation Corp., Spruce Pine, N. C., were presented in the trade press.[6] The process was developed by two associated companies—Feldspar Milling Co., Burnsville, N. C., and North Carolina Feldspar Corp., Erwin, Tenn.—in cooperation with Tennessee Valley Authority and the North Carolina State College Minerals Research Laboratories at Asheville.

CONSUMPTION AND USES

Crude Feldspar.—Many of the merchant grinders also mine feldspar, either themselves or through affiliated firms. A large part of the crude feldspar mined, however, is obtained from small operators who sell their product principally to the merchant mills. The tonnage of feldspar and feldspathic rock treated in flotation plants is increasing.

Most of the consumers of feldspar buy material already ground, sized, and ready for use in their products from the merchant grinders. Some pottery and enamel manufacturers and soapmakers, however, purchase all or part of their requirements in crude form and crush or grind it to their own specifications in their own mills. Some Canadian crude spar is purchased direct by consumers in this country. Manufacturers of artificial teeth annually consume a small tonnage of very carefully selected crude spar, which must be free from grit and is marketed at a considerable premium over No. 1 grade commercial feldspar.

Ground Feldspar.—The ceramic industries in 1949 consumed 99 percent of the feldspar ground in merchant mills in the United States, compared with 98 percent in 1948 and 1947. Glass represented 52

percent of the total; pottery, 41 percent; enamel, about 6 percent; and other uses, including soaps and abrasives, 1 percent. Shipments to glass factories and pottery manufacturers in 1949 decreased 26 and 22 percent, respectively, compared with 1948, and sales to makers of enamelware were slightly above the 1948 figure.

In 1949 ground feldspar was shipped into at least 30 States and 5 foreign countries. The larger consuming areas, however, were confined to six States—Pennsylvania (15 percent of the total shipments), Ohio (14 percent), Illinois (13 percent), New Jersey (11 percent), West Virginia (8 percent), and Indiana (7 percent)—totaling 68 percent of all sales. Other States consuming fairly large amounts of ground feldspar were New York, Maryland, Oklahoma, Texas, and Wisconsin. The only important State for which an increase was reported was Oklahoma. California and Ohio showed only slight decreases in 1949 compared with 1948, and other States for which figures are given were substantially less than in 1948.

Ground feldspar shipped from merchant mills in the United States, 1944–49, by destinations, in short tons

Destination	1944	1945	1946	1947	1948	1949
California	9,788	8,735	8,641	7,395	8,406	8,385
Illinois	49,434	53,114	68,737	72,212	66,064	51,202
Indiana	40,057	47,321	47,756	44,864	37,774	25,962
Maryland	7,593	9,411	18,374	19,531	19,832	16,371
Massachusetts	3,508	3,258	3,009	3,906	4,437	1,944

Other destinations [2]	25,132	35,189	36,096	37,961	49,061	44,226
Total	343,201	381,728	470,199	482,700	506,451	396,797

[1] Included with "Other destinations"; separate figure for State not available.
[2] Includes Alabama, Arkansas, Colorado, Connecticut, District of Columbia, Florida, Hawaii, Kentucky, Louisiana, Michigan, Minnesota, Mississippi, Missouri, Oklahoma (1944–45), Puerto Rico, Rhode Island, South Carolina, Tennessee, Texas, and Washington and shipments that cannot be segregated by States; also small shipments to Canada, England, Mexico, and other countries.

PRICES

Quotations on crude feldspar do not appear in the trade journals. Average values per ton, however, are computed from the annual questionnaires received from producers by the Bureau of Mines. In 1949 the average realization for all feldspar mined in the United States was $6.17 per long ton, an 11-percent increase over that for 1948 ($5.57). Average values for Arizona and South Dakota declined, but all other important producing States had higher realizations in 1949 than in 1948, the increases ranging from 2 to 4 percent for Georgia, Maine, and Virginia, up to 9 percent for North Carolina, 13 percent for New Hampshire, 16 percent for Connecticut, and 38 percent for Colorado.

The average realization per short ton for ground feldspar in 1949 rose to $14.50 compared with $12.76 in 1948, an increase of 14 percent. Most States had higher average values per ton in 1949 than in 1948,

and the five States indicating declines showed decreases of only 1 to 4 percent. The relative increases in realization varied from 3 percent for Colorado to 27 percent for North Carolina-Tennessee. Average values for the larger producing States ranged from $10.51 for Colorado to $23.24 for New York.

According to E&MJ Metal and Mineral Markets, quotations on ground feldspar in 1949 did not change from 1948 and were as follows: North Carolina, bulk carlots, 200-mesh, $18.50 per short ton; 325-mesh, $22.50; glass spar, No. 17, $12.50, and semigranular, $11.75. (Bags and bagging added $3 per ton to bulk quotations.) Virginia feldspar also remained at the same levels during 1949 as follows: No. 1, 230-mesh, $18.50 per ton, and 200-mesh, $17.50; No. 17 glassmakers' spar, $11.75, and No. 18, $12.50. Enamelers' spar was quoted at $15 to $17 throughout the year.

FOREIGN TRADE [7]

Imports for consumption of crude feldspar in 1949 totaled 15,826 long tons valued at $107,925, a drop of 49 percent in quantity and 51 percent in value compared with 1948. The tonnage of crude spar imported was the smallest since 1945, and the value the lowest since 1944. No imports of ground feldspar were reported in 1949.

Feldspar imported for consumption in the United States, 1945–49

[U. S. Department of Commerce]

Year	Crude		Ground		Year	Crude		Ground	
	Long tons	Value	Short tons	Value		Long tons	Value	Short tons	Value
1945	14,924	$114,917			1948	31,047	$219,785	(1)	$328
1946	16,365	[2] 127,517	(1)	$2	1949	15,826	107,925		
1947	16,685	124,587							

[1] Less than 1 ton.
[2] Revised figure.

As reported by the merchant grinders, the tonnage of ground feldspar destined for export in 1949 totaled 4,228 short tons, compared with 1,434 and 1,750 tons in 1948 and 1947, respectively. Countries of destination were Canada, Mexico, Peru, Belgium, and United Kingdom.

Cornwall Stone.—Imports for consumption of unmanufactured Cornwall stone in 1949 totaled 772 long tons, a large decline from the 1948 figure. Imports of ground Cornwall stone also were much less than in 1948. Both unmanufactured and ground Cornwall stone originate solely in the United Kingdom.

[7] Figures on imports are compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

NEPHELINE SYENITE

Nepheline syenite is a quartz-free crystalline rock consisting largely of nephelite and albite and microcline feldspar. Impurities may be the iron-bearing minerals black mica and magnetite and other minerals, such as zircon and corundum. Used originally almost entirely in glass manufacture, substantial quantities now are consumed in making pottery.

Domestic Deposits.—Nepheline syenite occurrences in New Jersey, Arkansas, and other American localities have been investigated, but all the domestic material found thus far in any appreciable tonnage has contained too much iron for ceramic purposes.

Uses.—The first and largest use for nepheline syenite is in glass manufacture, where its high alumina content is especially desirable. Following extensive research, its applications have spread into the enamel and especially the pottery trades in rising volume, both as a body component and as a part of the glaze. It is claimed that use of nepheline syenite in floor and wall tile compositions, sanitary ware, semivitreous bodies, and other ceramic products results in lower firing temperatures, greater firing range, and savings in fuel cost. Reactions of nepheline syenite-talc mixtures in low-temperature vitrified bodies also have been studied.[8] Although theoretically having piezoelectric properties, natural nepheline has not been so used because of its small, imperfect crystals.[9]

Prices.—Quotations on crude nepheline syenite are not reported in trade journals; however, crude values for this material may be approximated in the average values per ton of imports for consumption in the United States. These values were: 1945, $3.77; 1946, $3.98; 1947, $3.57; 1948, $4.01, and 1949, $4.07. According to the Oil, Paint and Drug Reporter, quotations on ground nepheline syenite during 1949 were as follows: Glass grade (24-mesh), bulk, f. o. b. Rochester, N. Y., $14.25; and pottery grade (200-mesh), bulk, f. o. b. Rochester, N. Y., $18.25. Nepheline syenite in bags was $3 per ton higher than bulk.

[9] Waesche, Hugh H., Importance and Application of Piezoelectric Minerals: Mining Eng. (Mining Trans.), vol. 1, No. 1, January 1949, pp. 12–17.

Foreign Trade.—Imports of crude nepheline syenite in 1949 were 23 percent less than in 1948. Imports of ground nepheline syenite, on the other hand, rose nearly 150 percent to a new high. The increase in receipts of ground nepheline almost matched the decrease in imports of crude. Average value per ton (foreign market value) of ground nepheline syenite imported was $13.22 in 1949. Both crude and ground material were imported wholly from Canada.

Nepheline syenite imported for consumption in the United States, 1945–49

[U. S. Department of Commerce]

Year	Crude		Ground		Year	Crude		Ground	
	Short tons	Value	Short tons	Value		Short tons	Value	Short tons	Value
1945	51,735	$194,975	1,073	$11,461	1948	53,570	$214,747	7,577	$130,860
1946	51,852	206,613	1,018	11,137	1949	41,215	167,567	18,779	248,224
1947	54,382	194,283							

Canada.—Supplies of nepheline syenite consumed in the United States have originated almost exclusively from the mines and plants of America Nepheline, Ltd., near Lakefield, Ontario, Canada. Most of this material has been exported in crude form and processed at the firm's Rochester, N. Y., mill. Although the total tonnage exported in 1949 did not vary greatly from that exported in 1948, the quantity of ground material in 1949 was nearly two and one-half times that in 1948. This was due to the larger utilization of the capacity of the new grinding mill placed in operation during 1948 at Lakefield. A gradual shift of grinding operations to Lakefield is planned, with an eventual closing of the Rochester plant.

Europe and Asia.—Deposits of nepheline syenite in northern European U. S. S. R. have been tested as a source of alumina, and as raw material for the manufacture of enamel and glass, but no production data are available. Other deposits have been reported in Finland and India.

APLITE

Production of aplite in 1949 declined compared with 1948. The average value per ton increased slightly. Virtually all of the aplite produced was consumed in the manufacture of glass, particularly container glass. The only producers of aplite are Dominion Minerals, Inc., Piney River, Va., and Carolina Mineral Co., Inc., Kona, N. C., in Amherst and Nelson Counties, Va., near Piney River. The Bureau of Mines is not at liberty to publish output or sales data. Announcement has been made of the establishment of an undergraduate fellowship in the Department of Glass Technology, New York State College of Ceramics, to investigate and develop uses for aplite.[10]

[10] Glass Industry, vol. 31, No. 2, February 1950, p. 111.

TECHNOLOGY

Continuing the active interest in feldspar and its applications, the Committee (C–21) on Ceramic Whitewares of the American Society for Testing Materials (ASTM) has inaugurated a program of research on the fundamental properties of feldspar.[11] The role of feldspar as a flux in whiteware manufacture was described and the merits of potash and soda spars were discussed.[12] The importance of feldspar in the making of porcelain enamel was reported.[13] Discussions of the raw materials (including feldspar) used in the ceramic industries were presented.[14]

The use of slag as a competitive material in the glass batch apparently is growing,[15] and tests of dolomite as a substitute for feldspar in the making of floor tile have been reported.[16] The composition of stoneware glazes and the reactions of the various components including feldspar were studied.[17] The difficulties in drilling quartz-feldspar intergrowths (graphic granites) were reported.[18]

The general features, internal structure, mineralogy, and origin of the granitic pegmatites in the principal pegmatitic areas in the United States were presented in a recently published monograph.[19] A study of some of the perthite pegmatites of the Black Hills, South Dakota, was published.[20]

WORLD REVIEW

The world output of feldspar in 1949 was estimated at 660,000 metric tons, a 13-percent decrease compared with 1948. Not included in the total is production in China, Peru, and U. S. S. R., for which countries no data are available.

Although United States, Canadian, Norwegian, and Italian output each showed a considerable decline, production in Australia, Finland, Germany (Bavaria), and the Union of South Africa registered gains, not large enough in the aggregate, however, to offset the smaller outputs for other chief producing countries. The ratio of United States production to total known estimated world output in 1949 was 57 percent compared with 62 percent in 1948.

Ferro-Alloys

By Norwood B. Melcher

GENERAL SUMMARY

A SHARP decline in the production and shipment of ferro-alloys in 1949 resulted in part from a 12-percent drop in the output of steel ingots and castings during the year but more particularly from a 26-percent decline in the shipments of alloy steels during the year. Consequently, such alloys as manganese and silicon, which are related to the total output of steel, declined far less than those alloying materials which are used primarily for their alloying effects. Manganese and silicon may both be considered as scavengers in that they either remove objectionable impurities or render them relatively harmless. Silicon is used mainly in removing oxygen from steel, and manganese removes oxygen and sulfur, but more important, it combines with sulfur in steel and minimizes the difficulties in hot rolling which results when sulfur is combined with iron rather than manganese.

Ferro-alloys are peculiar in their use in that they have no particular value in themselves and do not reach the ultimate consumer as such. Their main use is in the manufacture of various types of steels, and in fact the production of modern steels depends upon the availability of these materials. Hence, with few exceptions these alloying materials receive the highest priority as strategic materials and are on the National Stockpile list. The exceptions are silicon, phosphorus, titanium, and zirconium, which are considered the only ones available in sufficient quantities for an emergency period. As would be suggested from this fact, most of these critical materials are obtained largely from foreign sources. Silicon is produced in the United States and nearby Canada in tonnages sufficient to meet all anticipated requirements, and the bulk of the vanadium requirements are obtained from domestic sources. The United States produces about 90 percent of the world supply of molybdenum, but the fact that a large portion of the United States supply of this metal is obtained from one large underground mine requires that this material be given special consideration. Ferro-alloys are produced in blast furnaces, electric furnaces, and by aluminothermic processes.

Of all the ferro-alloys, only one containing a high percentage of the rare alloying metal, ferromanganese, is produced mainly in blast furnaces, although the low-carbon ferromanganese is produced by electric methods. Spiegeleisen, the 20-percent manganese material, is produced by blast furnaces, and the lower grades of ferrosilicon (under 13 percent) are produced by this method. Most of the molybdenum alloys and a small part of the ferrotitanium are produced by the aluminothermic process, where powdered aluminum is used as a reducing agent.

The ferro-alloying ores of metals are discussed in detail in chapters of this volume dealing with particular metals. These chapters are

Chromium, Manganese, Molybdenum, Titanium, Tungsten, Vanadium, and Minor Metals.

PRODUCTION AND SHIPMENTS

The production of ferro-alloys in 1949 totaled 1,544,442 net tons, compared with 1,892,521 tons in 1948, a decrease of 18 percent. In 1949, ferro-alloys were made in 13 blast-furnace plants, 29 electric-furnace plants, and 2 aluminothermic-furnace plants. In addition, 1 plant using electric furnaces produced ferrosilicon, and 6 produced ferrophosphorus as a byproduct. Shipments of all classes of ferro-alloys from furnaces decreased 27 percent in quantity but only 19 percent in value from 1948, indicating the higher level of prices during the year. Pennsylvania again led all other States in production and shipments of ferro-alloys, producing 31 percent of the United States total tonnage and 39 percent of the value, compared with 33 percent and 40 percent, respectively, in 1948. This State, however, decreased its production 23 percent from 1948. New York was the second largest State from a standpoint of production, supplying 15 percent of the tonnage and 20 percent of the value. Production and shipments of ferro-alloys also were reported from Alabama, California, Florida, Indiana, Iowa, Kentucky, Montana, New Jersey, Ohio, Oregon, South Carolina, Tennessee, Virginia, Washington, and West Virginia.

Ferro-alloys produced and shipped from furnaces in the United States, 1948–49

[1] Silicomanganese, manganese briquets, ferrochromium, ferrocolumbium, ferroboron, zirconium-ferrosilicon, and miscellaneous ferro-alloys.

Ferromanganese.—The ferromanganese produced in 1949 averaged 78.33 percent manganese and came from four electric and seven blast-furnace plants. Of the manganese ore used in 1949 for the manufacture of ferromanganese, 90 percent was foreign compared with 94 percent in 1948. During the year, 560,180 net tons were shipped from furnaces, whereas consumption totaled 617,645 tons, the difference being made up from imported material. The steel industry in using 13.2 pounds of contained manganese per ton of steel ingots produced in 1949, used most of the ferromanganese. High-carbon

Producers of ferro-alloys in the United States in 1949

Producer	Plant	Alloy
American Agricultural Chemical Co.	South Amboy, N. J.	Ferrophosphorus (byproduct).
Anaconda Copper Mining Co.	Anaconda, Mont. Black Eagle, Mont.	Ferromanganese.
Bethlehem Steel Co.	Johnstown, Pa.	Do.
Climax Molybdenum Co.	Langeloth, Pa.	Ferromolybdenum, calcium molybdate, molybdenum oxide, oxide briquets, molybdenum trioxide, sodium molybdate, ferrotungsten, molybdenum silicide, ammonium molybdate, molybdenum sulphide, cobalt molybdenum.
Electro Metallurgical Co.	Alloy, W. Va. Ashtabula, Ohio Columbiana, Ohio Holcomb Rock, Va. Niagara Falls, N. Y. Portland, Oreg. Sheffield, Ala.	Ferromanganese, silicomanganese, manganese briquets, ferrosilicon, silicon briquets, zirconium-ferrosilicon, ferrochromium, chromium briquets, ferrotungsten, ferrovanadium, ferroboron, ferrocolumbium, ferrotitanium, ferromolybdenum.
Globe Iron Co.	Jackson, Ohio	Silvery pig iron.
Hanna Furnace Corp.	Buffalo, N. Y.	Do.
Inland Steel Co.	East Chicago, Ind.	Spiegeleisen.
Jackson Iron & Steel Co.	Jackson, Ohio	Silvery pig iron.
Keokuk Electro-Metals Co.	Keokuk, Iowa	Ferrosilicon, silvery pig iron.
E. J. Lavino & Co.	Reusens, Va. Sheridan, Pa.	Ferromanganese.
Metal & Thermit Corp.	Carteret, N. J.	Ferrotitanium.
Molybdenum Corp. of America	Washington, Pa.	Ferrotungsten, ferromolybdenum, molybdic oxide, ferroboron, manganese boride.
Monsanto Chemical Co.	Anniston, Ala. Columbia, Tenn.	Ferrosilicon (byproduct), ferrophosphorus, (byproduct).
New Jersey Zinc Co.	Palmerton, Pa.	Spiegeleisen.
Ohio Ferro-Alloys Co.	Philo, Ohio. Tacoma, Wash.	Ferrosilicon, simanal, ferrochromium.
Oldbury Electro-Chemical Co.	Niagara Falls, N. Y.	Ferrophosphorus (byproduct).
Permanente Metals Corp.	Permanente, Calif.	Ferrosilicon.
Pittsburgh Metallurgical Co.	Charleston, S. C. Niagara Falls, N. Y. Calvert City, Ky.	Ferrosilicon, silvery pig iron, ferrochromium, silicomanganese.
Sloss-Sheffield Steel & Iron Co.	N. Birmingham, Ala.	Ferromanganese.
Tennessee Products & Chemical Corp. (Southern Ferro-Alloys Div.).	Chattanooga, Tenn.	Ferromanganese, ferrosilicon, silicon briquets.
Tennessee Valley Authority	Muscle Shoals, Ala.	Ferrophosphorus (byproduct).
Titanium Alloy Mfg. Div., National Lead Co.	Niagara Falls, N. Y.	Ferrotitanium.
U. S. Steel Corp. subsidiaries	Clairton, Pa. Etna, Pa. Duquesne, Pa. Gary, Ind.	Ferromanganese, spiegeleisen.
Vanadium Corp. of America	Niagara Falls, N. Y. Bridgeville, Pa.	Ferrosilicon, silicon briquets, alsifer, ferrochromium, ferrovanadium, ferrotitanium, grainals, ammonium meta vanadette, aluminum ferro-alloy, titanium aluminum.
Victor Chemical Works	Mt. Pleasant, Tenn.	Ferrophosphorus (byproduct).
Virginia-Carolina Chemical Corp.	Nichols, Fla.	Do.

ferromanganese is satisfactory for the bulk of the steel production, whereas the low-carbon alloy is used in such steels as stainless, where very low carbon is essential. Most of the ferromanganese imported in 1949 originated in Canada and Norway, but very small quantities came from Japan, China, and Korea.

Spiegeleisen.—Spiegeleisen is used for essentially the same purposes as ferromanganese but is in less demand due to the longer time required to melt and remove carbon from the product to introduce equivalent quantities of manganese metal to steel. More carbon is added to the bath per unit of manganese when spiegeleisen is used. The production of this alloy continued to decrease in 1949 dropping off 31 percent from the previous year. Shipments dropped off even more, being 51 percent less in quantity and 44 percent less in value than in 1948. This is not a desirable trend, as an equivalent require-

ment for manganese metal is thereby necessarily supplied by ferromanganese, which in turn requires the strategically important high-grade manganese ore. Shipments of spiegeleisen from furnaces in 1949 totaled 53,888 tons valued at $2,972,653 f. o. b. furnaces, or $55.16 per ton, compared with $48.29 per ton in 1948 and $39.99 in 1947. Three-tenths pound of metallic manganese in the form of spiegeleisen was used per ton of steel produced in 1949.

Ferrosilicon.—The production of ferrosilicon from a standpoint of tonnage constitutes the largest single production segment in the ferro-alloy industry. In fact, 42 percent of the total ferro-alloy production in 1949 consisted of this alloy. This total, as can be observed from an accompanying consumption table, includes numerous grades of alloys containing silicon which are unlike and are used for many purposes. For example, silvery pig iron included in the ferrosilicon figures is produced largely in blast furnaces and is used mainly in the iron-foundry industry, whereas the standard ferrosilicon (50 percent) is material used in the manufacture of steel. In 1949 the blast-furnace product averaged 9.8 percent Si as in 1948, while electric-furnace output, mostly ferrosilicon containing over 20 percent Si, averaged

Consumption of ferrosilicon, silicon metal, and miscellaneous silicon alloys in the United States in 1949, by industries, in net tons

Alloy	Steel ingots and castings [1]	Steel castings [1]	Miscellaneous	Total
Silvery pig iron: 5-20 percent silicon	61,527	16,194	249,314	327,035
Ferrosilicon:				
50 percent silicon	132,993	10,436	9,450	152,879
75 percent silicon	28,262	135	2,441	30,838
Other grades [2]	32,231	2,856	38,769	73,856
Total	255,013	29,621	299,974	584,608

[1] Data for castings made by companies that also produce steel ingots are included with "Steel ingots and castings" and excluded from "Steel castings."
[2] Includes grades of ferrosilicon not listed separately, silicon metal, and miscellaneous silicon alloys.

40 percent. Shipments of all grades of ferrosilicon (including silvery pig iron) totaled 590,168 net tons valued at $55,415,405. Of this 255,013 net tons of ferrosilicon and miscellaneous silicon alloys were consumed in the manufacture of steel ingots and castings, as published by the American Iron and Steel Institute. Fifty-two percent (132,993 net tons) was of the standard 50-percent grade, 61,527 net tons were silvery pig iron, and 28,262 tons the 75-percent grade. "Other grades" constituted the remaining 32,231 tons. The most important grade of ferrosilicon is the standard 50 percent, which is employed as a deoxidizer and solidifier in manufacturing most grades of killed and semikilled steel. Only a small quantity of alloy is used in iron foundries and other industries. Alloys containing 75-percent silicon and miscellaneous silicon alloys are used in ladle additions in gray-iron foundries and in the manufacture of high-silicon steel for use in electrical equipment and high-silicon spring steel. The accompanying table shows the consumption of the various grades of silicon alloys according to the major consuming industry groups.

Ferrophosphorus.—All ferrophosphorus in 1949 was produced in

electric furnaces as a byproduct in the manufacture of phosphate fertilizers and other chemicals. Shipments of ferrophosphorus fell precipitously during the year as a result of a comparable drop in the export market of this material. Exports, which had reached the record high of 52,988 net tons in 1948, were only 5,050 tons in 1949. Thus even with a slight increase in production of this alloy, shipments totaled only 19,874 tons valued at $748,086 compared with 72,-453 tons valued at $2,006,254 in the previous year.

Ferrotungsten.—The ferrotungsten produced in the United States during 1949 was made in the electric furnaces using both foreign and domestic ores. The total consumption of tungsten concentrates in the United States during the year was 5,210 net tons (60 percent WO_3 basis), 2,472 tons of which were consumed in the manufacture of ferrotungsten. The domestic material was obtained from nine States and Alaska in 1949, but three States—Nevada, North Carolina, and California—supplied 86 percent of the total. Imports for consumption of tungsten ores and concentrates in 1949 were equivalent to 6,592 net tons of 60 percent WO_3, a 17-percent decrease from 1948. These ores and concentrates came from 16 foreign countries in 1949; but 3—China, Korea, and Thailand—supplied 87 percent of the total.

Ferrochromium.—All of the ferrochromium output in the United States in 1949 was produced in electric furnaces and mainly from foreign ores. Generally speaking, ferrochromium is produced in two separate grades—the high-carbon, which contains more than 2 percent, and various low-carbon grades, which contain less than 2 percent with some as low as 0.03 maximum carbon. Stainless steels and high-temperature alloys are the main users of the low-carbon grade. Consumption of ferrochromium in the United States in 1949 dropped to 87,764 short tons compared with 122,753 tons in 1948 and 113,491 tons in 1947. This consumption was reported by consumers which normally use about 85 percent of the total. Exports and imports both declined from the previous year.

Ferromolybdenum.—The ferromolybdenum produced in 1949 was made by the aluminothermic process and in electric furnaces using domestic concentrates. The alloy was produced in only two plants during the year; these are in Langeloth, Pa., and Washington, Pa.

Molybdic Oxide, Calcium Molybdate, and Molybdenum Compounds.—Molybdenum compounds used in alloying agents in the production of iron and steel are included with ferro-alloys. These materials are much less expensive than ferromolybdenum and consequently are used to a greater extent. As with ferromolybdenum, virtually all these compounds are made from domestic raw materials.

Ferrotitanium.—In 1949 most of the ferrotitanium was produced in electric furnaces, but a small quantity was made by the aluminothermic process. The ferrotitanium produced in 1949 contained a higher percentage of alloy high in titanium, as indicated by the fact that the average of all grades in 1949 was 23.4 percent Ti, compared with 19.5 percent in 1948. Both foreign and domestic ores (ilmenite and rutile) were consumed in its manufacture. Ferrotitanium is used as a deoxidizer and scavenger in steel manufacture. When employed as a deoxidizer, ferrotitanium is charged in combination with silicon or some other deoxidizing agent. The titanium alloy is added as a final

purifier. As an alloying agent, ferrotitanium prevents intergranular corrosion.

Ferrovanadium.—All ferrovanadium produced in 1949 was made in electric furnaces, and both foreign and domestic ores were used in its manufacture. This alloy averaged 50 percent vanadium in 1949, compared with 48 percent in 1948 and 45 percent in 1947.

Ferrocolumbium.—Ferrocolumbium is used in stainless steel to prevent intergranular corrosion. It also reduces air hardening and oxidation at high temperature in chromium steel. In 1949 the output of ferrocolumbium averaged 57 percent columbium and was produced in electric furnaces.

Zirconium-Ferrosilicon.—The zirconium-ferrosilicon produced in 1949 averaged 14 percent Zr, as in the previous year. Zirconium, a powerful deoxidizer and scavenger, reduces hardening and thereby improves deep-drawing properties of sheet steel. It is used instead of ordinary ferrosilicon and is more effective. Zirconium, like manganese, will combine with sulfur in the steel, eliminating or reducing the harmful property of hot shortness. The addition of relatively high percentages of zirconium (over 0.10 percent) will result in fine grain sizes and will improve hardenability.

Silicomanganese.—This alloy is used to make manganese additions to steel and is used in killed steels only, because of the silicon present.

Manganese Briquets.—The foundry industry is the principal user of manganese briquets, which are added to molten iron to overcome the harmful effects of sulfur and to act as a deoxidizer and scavenger. Each of these briquets contains exactly 2 pounds of manganese; therefore they can be added without the inconvenience of weighing the material.

FOREIGN TRADE [1]

Ferromanganese continued to be the main ferro-alloy import commodity in 1949. Most of this ferromanganese was received from Canada and Norway and was manufactured from ores exported from Gold Coast. Consequently, the receipts of manganese ore as such from Gold Coast failed to represent the full picture. The alloy received from Norway and Canada was equivalent to more than 120,000 tons of manganese ore during 1949.

Exports of ferro-alloys dropped to barely one-fifth of the 1948 total with decreases noticeable in most of the alloys. The largest tonnage drops, however, were in ferrophosphorus and ferromanganese.

Fluorspar and Cryolite

By Hubert W. Davis

GENERAL SUMMARY

SHIPMENTS of fluorspar from mines in the United States, which established a peacetime record in 1948, declined 29 percent in 1949, and imports, which reached an all-time high in 1948, dropped 14 percent. Domestic shipments in 1949 were the smallest since 1940, but imports have been exceeded by only two other years. Production of finished fluorspar also declined substantially. The smaller demand for fluorspar in 1949 was caused largely by a 15-percent decline in consumption—which resulted chiefly from a strike in the steel industry and from a lower level of operations in the hydrofluoric-acid and glass industries—and partly by an 11-percent reduction in consumers' inventory.

Illinois maintained its rank as the premier producer of fluorspar in 1949 by supplying 51 percent of the total domestic shipments. However, shipments from Illinois were 30 percent less than in 1948 and the smallest since 1940. Montana and Texas were the only States to show gains in shipments in 1949.

Calcium fluoride was produced by the Tennessee Valley Authority as a byproduct of a new fluorine-recovery system under development since May 1949 at its experimental fused tricalcium phosphate fertilizer units at Godwin, Tenn.

For the ninth consecutive year, Mexico has been the largest source of foreign fluorspar to the United States, and in 1949 it supplied 61 percent of total imports. However, imports from Mexico were 27 percent smaller than in 1948. Substantially larger imports were received from Italy and Spain. For the first time since 1940, fluorspar was received from France.

The steel industry continued to be the predominant user of fluorspar and absorbed proportionately more (58 percent) of the total consumed in 1949 than in 1948 (57 percent). The average consumption of fluorspar per long ton of basic open-hearth steel produced declined slightly from 5.86 pounds in 1948 to 5.85 pounds in 1949. The hydrofluoric-acid industry, the second largest utilizer of fluorspar, consumed 17 percent less than in 1948 and accounted for 26 percent of the total in 1949, the same share as in 1948. Consumption of fluorspar by the glass and enamel trades in 1949 declined for the second consecutive year and was 21 percent smaller than in 1948. Less fluorspar was also consumed in 1949 than in 1948 at iron foundries, nonferrous smelters, and cement plants, but more was used at plants making ferro-alloys and special fluxes.

Deliveries of fluorspar to consumers in the United States totaled 325,780 short tons in 1949 (235,921 tons from domestic mines and 89,859 tons from foreign sources). In 1948 deliveries to consumers totaled 442,336 tons (331,105 tons from domestic mines and 111,231 tons from foreign sources). Total deliveries to steel plants in the United States declined to 188,047 tons (269,304 tons in 1948), those to hydrofluoric-acid plants decreased to 86,779 tons (106,857 tons in

1948), and those to glass and enamel plants fell to 34,482 tons (45,602 tons in 1948).

Salient statistics of fluorspar in the United States, 1940–49, in short tons

Year	Shipments from domestic mines	Foreign trade		Consumption	Industry stocks at end of year		
		Imports for consumption	Exports		Domestic mines [1]	Consumers' plants	Total
1940	233, 600	11, 873	8, 482	218, 500	43, 866	102, 100	145, 966

1949	236, 704	95, 619	802	345, 221	37, 039	130, 621	[2] 167, 660

[1] Finished fluorspar only.
[2] In addition, importers held 11,000 tons in 1949 (none in 1940–48).

The average composite selling price ($33.19 a short ton) of all grades of fluorspar (both domestic and foreign) delivered to consumers in the United States in 1949 was $1.05 more than in 1948.

The total quantity of fluorspar shipped from mines and imported into the United States from about 1870 through 1949 was approximately 9,141,000 short tons, comprising about 82 percent from domestic mines and 18 percent from foreign sources.

PRODUCTION AND SHIPMENTS

Production of finished fluorspar totaled 236,400 short tons in 1949, including 111,247 tons of flotation concentrates; in addition, crude ore equivalent to about 9,200 tons of finished fluorspar was mined but not milled in 1949. Thus, total production (expressed in terms of finished fluorspar) was 245,600 tons in 1949, compared with 333,900 tons in 1948. Of the mine output in 1949, 5 mines (producing over 10,000 tons each) supplied 60,800 tons, or 25 percent; 11 mines (producing 5,000 to 10,000 tons each) supplied 74,500 tons, or 30 percent; 32 mines (producing 1,000 to 5,000 tons each) supplied 86,500 tons, or 35 percent; and 7 mines (producing 500 to 1,000 tons each) supplied 4,900 tons, or 2 percent. Thus, 55 mines produced 226,700 tons, or 92 percent of the total. Of the remaining output (18,900 tons, or 8 percent), some (in quantities ranging from a few tons to 500 tons) came from an undetermined number of small mines and prospects, but much was derived from treated tailings from previous milling operations.

In 1949, mines operated by consumers produced 61,900 tons of finished fluorspar, compared with 89,600 tons in 1948.

Fluorspar shipments from domestic mines in 1949 aggregated 236,704 short tons valued at $8,266,754, decreases of 29 percent in quantity and 26 percent in value from 1948. Of the 1949 total, 53,243 tons were shipped by river or river-rail for delivery to consumers, compared with 71,696 tons in 1948.

Illinois (51 percent) and Kentucky (27 percent) supplied 78 percent of the fluorspar shipped in 1949, as in 1948. Shipments from Illinois and Kentucky were 28 percent less than in 1948, compared with a loss of 29 percent from other producing States.

The average value of all grades of domestic finished fluorspar shipped in 1949 ($34.92) established a new peak and was $1.08 more than the previous high of 1948.

Fluorspar shipments in 1949 comprised 121,163 tons of fluxing gravel (including 6,948 tons of flotation concentrates, which were

[1] Fluxing gravel includes (and flotation concentrates exclude) the following quantities of flotation concentrates blended with fluxing gravel: 1948, 16,666 tons; 1949, 6,948 tons.
[2] Includes pelletized gravel.

blended with fluxing gravel) and foundry lump, 115,540 tons of ground and flotation concentrates, and 1 ton of acid lump. The bulk of the fluxing-gravel and foundry-lump fluorspar was shipped to steel plants and iron foundries, but a comparatively small tonnage moved to plants making cement, ferro-alloys, nickel, basic refractories, and fluxing compounds and to smelters of secondary metals. Of the ground and flotation concentrates shipped in 1949, hydrofluoric-acid plants took 61 percent and glass and enamel plants 28 percent; the remainder went chiefly to aluminum- and magnesium-reduction works; to manufacturers of steel, ferro-alloys, and welding rods; and to smelters of secondary metals.

SHIPMENTS, BY USES

As is evident from the accompanying table and figure 1, the predominant purchaser of fluorspar is the steel industry, which also consumes substantial quantities of hydrofluoric acid and sodium fluoride, for which fluorspar is the basic material.

Fluorspar shipped from mines in the United States, by uses, 1948–49

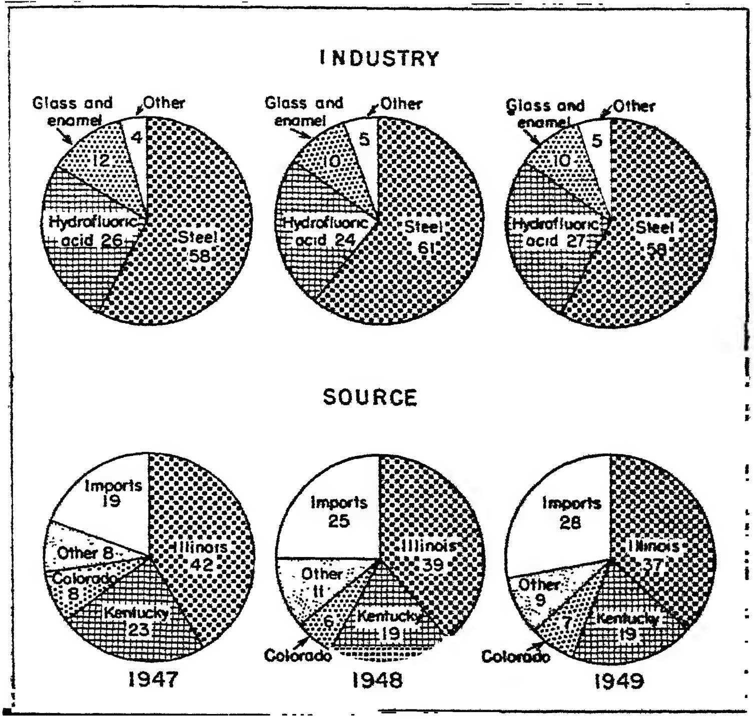

FIGURE 1.—Fluorspar sales (domestic and foreign) to consumers in the United States, 1947–49, by consuming industries and sources, in percent.

STOCKS AT MINES

According to the reports of producers, the quantity of fluorspar in stock at mines or shipping points at the close of 1949 totaled 121,516 tons, or 21 percent more than in 1948. These stocks comprised 37,039 tons of finished fluorspar and 84,477 tons of crude fluorspar (calculated to be equivalent to 36,000 tons of finished fluorspar).

Stocks of fluorspar at mines or shipping points in the United States, by States, at end of year, 1947–49, in short tons [1]

State	1947		1948		1949

[1] Fluorspar used in making artificial cryolite and aluminum fluoride (aluminum raw materials) is included in the figures for hydrofluoric acid, which is an intermediate in their manufacture.
[2] Figures on consumption represent fluorspar used as a flux; see footnote 1.

Production of basic open-hearth steel and consumption and stocks of fluorspar (domestic and foreign) at basic open-hearth steel plants, 1945–49

	1945	1946	1947	1948	1949
Production of basic open-hearth steel ingots and castings .... long tons	64,510,000	54,034,000	68,506,000	70,830,000	62,634,000
Consumption of fluorspar in basic open-hearth steel production .... short tons	176,488	145,631	189,773	207,342	183,045
Consumption of fluorspar per long ton of basic open-hearth steel made .... pounds	5.5	5.4	5.5	5.9	5.8
Stocks of fluorspar at basic open-hearth steel plants at end of year .... short tons	63,900	61,600	68,400	106,300	97,400

Fluorspar was reported consumed in 39 States and the District of Columbia in 1949, but 3 States—Illinois, Ohio, and Pennsylvania—used 182,969 tons, or 53 percent of the total consumption. Pennsylvania was again the chief consuming State; it ranked first in consumption of fluorspar both in steel and glass and sixth in the manufacture of hydrofluoric acid. Illinois maintained its rank as the largest consumer of fluorspar in hydrofluoric acid in 1949.

The accompanying table shows, so far as possible without revealing the figures of individual companies, the consumption of fluorspar by States in 1948 and 1949.

Fluorspar (domestic and foreign) consumed in the United States, by States, 1948–49, in short tons

State	1948	1949
Alabama, Georgia	12,435	10,517
Arkansas, Louisiana, Mississippi, North Carolina, South Carolina, Florida	17,269	22,457
California	10,612	10,050
Colorado, Iowa, Utah	15,308	14,578
Connecticut	950	662
Delaware, District of Columbia, New Jersey	26,984	24,380
Illinois	63,304	54,452
Indiana	30,077	24,250
Kansas, Nebraska, South Dakota, Wyoming	272	265

Missouri	4,041	2,790
New York	14,588	12,808
Ohio	67,725	56,451
Oklahoma	900	1,048
Oregon, Washington	2,358	1,965
Pennsylvania	97,664	72,066
Tennessee	1,084	389
Texas	12,387	5,296
Virginia	61	78
West Virginia	5,400	4,022
Total	406,269	345,221

REVIEW BY STATES

Alabama.—The Gilley fluorspar deposits in Cherokee County, Ala., have been examined and a report [1] issued.

Arizona.—Production of fluorspar in Arizona was 846 short tons in 1949, compared with 1,271 tons in 1948. The 1949 output came chiefly from Cochise County, but some came from Pima and Maricopa Counties. The fluorspar from Cochise County was from the Lone Star mine operated by Cooper Shapley, Jr., and that from Pima County was from the Mary Jane mine operated by Ira L. Moseley; the fluorspar from these mines was shipped to steel plants and to plants making ferro-alloys and special flux. The fluorspar from Maricopa County was from the Mammoth and surrounding veins operated by J. A. Campbell, the West End Spar mine operated by Isaac Campbell, and a property operated by Raymond Contreras; the fluorspar from these properties was shipped to steel plants. The Snowball fluorspar deposit in Maricopa County has been discussed.[2]

California.—The Industrial Minerals & Chemical Co., West Berkeley, Calif., ground some Nevada fluorspar, which it sold chiefly to local dealers; a small quantity was exported. The company also ground some Nevada fluorspar on a toll basis for Balfour, Guthrie & Co., Ltd., and sold it to an enamel plant.

Colorado.—Production of finished fluorspar in Colorado decreased to 22,400 short tons in 1949 from 27,800 tons in 1948. In addition, about 1,500 tons of crude ore equivalent to 600 tons of finished

[1] O'Neill, J. F., Investigation of Gilley Fluorspar Deposits, Cherokee County, Ala.: Bureau of Mines Rept. of Investigations 4665, 1950, 6 pp.

[2] Denton, T. C., and Kumke, C. A., Investigation of Snowball Fluorite Deposit, Maricopa County, Ariz.: Bureau of Mines Rept. of Investigations 4546, 1949, 13 pp.

fluorspar was mined but not milled in 1949. Thus, production (expressed in terms of finished fluorspar) totaled 23,000 tons in 1949, compared with 27,100 tons in 1948. Output in 1949 came from Boulder, Chaffee, and Mineral Counties.

Shipments of fluorspar from Colorado in 1949 declined for the fifth consecutive year and were the smallest since 1941; they were 22,324 tons, compared with 27,698 tons in 1948. The 1949 shipments comprised 16,998 tons of flotation concentrates and 5,326 tons of fluxing-gravel fluorspar.

The Ozark-Mahoning Co., operating a flotation mill near Jamestown, produced 3 percent more flotation concentrates in 1949 than in 1948, despite the fact that the flotation mill was inactive about 2 months because of a strike at a consumer's plant. The flotation-mill feed comprised ore chiefly from the Argo mine, but some was also contributed by the Afterthought, Blue Jay, and Emmett mines. These mines are in Boulder County and were operated by Harry M. Williamson & Son.

The flotation mill of the General Chemical Division, Allied Chemical & Dye Corp., near Jamestown, produced 24 percent less concentrates than in 1948. The flotation-mill feed comprised ore chiefly from the company-operated Burlington mine, but a small tonnage came from its Yellow Girl mine, both in Boulder County. A small quantity was purchased from other Boulder County mines.

Fluorspar, Inc., operated the flotation mill near Salida of the bankrupt United States Fluorspar, Inc., until August 6, when production was discontinued because of the poor condition of the mill and consequent high cost. The flotation-mill feed came from the Aksarben mine, also near Salida, in Chaffee County. The company was building a new mill.

J. H. & E. Lionelle produced a small tonnage of fluorspar from a property in Chaffee County in 1949; it was shipped to the local steel plant.

The Wagon Wheel Gap mine of the Colorado Fuel & Iron Corp. in Mineral County produced 43 percent less fluxing-gravel fluorspar in 1949 than in 1948. Much of the 1949 fluorspar requirements of the company steel plant at Pueblo was obtained from Mexico and from producers in Colorado and New Mexico.

Results of an investigation of the fluorspar deposits in Boulder County have been described.[3]

Illinois.—Illinois maintained its premier position as a fluorspar-producing State. Production of finished fluorspar was 118,300 short tons in 1949; about 90 percent came from Hardin County and the remainder from Pope County. In addition, some crude ore equivalent to 1,400 tons of finished fluorspar was mined but not milled in 1949. Thus, total mine production (expressed in terms of finished fluorspar) was 119,700 tons in 1949, compared with 172,700 tons in 1948. Some Kentucky fluorspar is milled in Illinois, and some Illinois fluorspar is milled in Kentucky; the finished fluorspar so recovered, as well as that shipped, is credited in the statistics to the State of origin. The Argo, Austin, Blue Diggings, Crystal, Deardorff, Douglas, East Green, Empire, Fairview, Geely Shaft, Interstate,

[3] Hild, J. H., and Ames, E. W., Investigation of Jamestown Fluorite Deposits, Boulder County, Colo.: Bureau of Mines Rept. of Investigations 4483, 1949, 10 pp.

Jefferson, Knox, Mahoning Shaft No. 2, Mahoning Shaft No. 5, Midway-North Boundary-Air Shaft-Hillside, Minerva, Pell Shaft, Redd, Rosiclare, South Boundary-Recovery Shaft, Victory, and West Green properties supplied about 97 percent of the fluorspar produced in Illinois in 1949. Most of the remainder came from many mines and prospects, chiefly the Baker, Big Creek, Hawkins Shaft, Humm, Lead Hill, Mahoning Shaft No. 4, Rose Creek, and Twitchell; some was recovered from tailings from previous milling operations.

Shipments of fluorspar from Illinois (120,881 tons) were 30 percent less than in 1948 and contributed 51 percent of the total domestic shipped. The 1949 shipments were the smallest since 1940. Of the 1949 total, 29,742 tons were shipped by river or river-rail to consumers, compared with 50,441 tons in 1948.

The Alcoa Mining Co. produced 25 percent less flotation concentrates in 1949 than in 1948. The mill feed comprised ore from the company-operated Argo, Blue Diggings, and Fairview mines. The ore from these mines is first treated in the company heavy-medium unit, which supplies an enriched product for flotation feed. The Argo-Blue Diggings vein system was worked through the Blue Diggings and Fairview shafts on the 300-, 400-, 500-, 600-, 700-, 800-, and 900-foot levels. A crosscut was driven from the 800-foot level to the bottom of the Fairview shaft, and a 75,000-gallon sump and pumping station were installed on the 800-foot level. Water from the Fairview shaft area is pumped to the 700-foot level, where it flows to the main pumping station at the Blue Diggings shaft. The company prospected by diamond drilling the Ruie Robinson property, but no fluorspar was disclosed.

The Crystal Fluorspar Co. produced 40 percent less finished fluorspar in 1949 than in 1948. Production in 1949 was obtained from the Crystal and Jefferson mines. At the Jefferson mine the sinking of a 100-foot winze from the 260-foot level was begun in December 1949.

The Ozark-Mahoning Co. produced 26 percent less fluorspar flotation concentrates in 1949 than in 1948. The mill feed in 1949 comprised ore from the Deardorff, East Green, Mahoning Shafts Nos. 2, 4, and 5, North Green, and West Green mines near Cave in Rock, Ill., the Delhi-Babb and Goering mines near Salem, Ky., and the Commodore mine near Marion, Ky., and some purchased ore, chiefly from the Mineral Ridge mine also near Salem. Production of finished fluorspar in 1949 comprised 81.9 percent acid grade, 16.7 percent pelletized gravel, and 1.4 percent filter cake; the filter cake was sold to local producers for blending with fluxing gravel. Production and shipments of finished fluorspar from the Delhi-Babb, Commodore, Goering, and Mineral Ridge mines have been credited to Kentucky in the statistics. The Ozark-Mahoning Co. was the largest producer of fluorspar in the United States in 1949. The company started sinking a 365-foot shaft on the Ida Oxford tract near Cave in Rock, Ill.

The Rosiclare Lead & Fluorspar Mining Co. operated the Eureka, Geely, Hawkins, Interstate, Midway-North Boundary-Air Shaft-Hillside, Pell, Rosiclare, and South Boundary-Recovery properties in 1949, but the Rosiclare was again the chief producing mine of the company. The company also purchased some fluorspar from local

producers. The ore from the company mines is mill feed for its heavy-medium, jig, and flotation mills. Production of finished fluorspar of all grades was 37 percent less than in 1948, and shipments were 28 percent smaller. The Rosiclare mine was allowed to flood to permit experimental pressure grouting in an effort to shut off a flow of underground water into the mine at a rate of 7,000 gallons per minute. An 1,800-gallon-per-minute, 660-foot head, deep-well type pump was installed in the Rosiclare shaft.

Operations at the mine and flotation mill of Minerva Oil Co. were at reduced rates during the first 9 months of 1949. As a result of increased demand during the last quarter of 1949, the mine and mill were operated on a 5-day and a 6-day week basis, respectively. Output of flotation concentrates was 27 percent smaller than in 1948, but sales were down 32 percent. The company continued prospecting with two to three drills on or near owned properties. Roof-bolting replaced most timbering in the mine. The company resumed sinking a 580-foot escape and service shaft. The mining practice at the Minerva mine has been described.[4]

Production in 1949 at the Douglas mine in Pope County, operated by the P. M. T. Mining Co., was 11 percent less than in 1948. The Redd mine operated by the Redd Mining Co. and Humm & Partain and the Empire mine operated by Egyptian Mining Co., J. P. & G. Mining Co., and G. & B. Mining Co.—both also in Pope County—and the Knox mine operated by Knox Spar Co., Rose Hill mine operated by Yingling Mining Co., Baker mine operated by Golconda Illinois Mining Co., Inc., Humm mine operated by C. C. Mackey, and Austin mine operated by A. B. C. Mining Co. and Blue Valley Mining Co.—all in Hardin County—were the largest of the many smaller mines worked in Illinois in 1949.

Results of an investigation of a deposit in Pope County have been described.[5]

Kentucky.—Production of finished fluorspar in Kentucky in 1949 (65,500 short tons) was 29 percent less than in 1948 and also 29 percent under the average for the 5 years 1944–48. Total mine production (expressed in terms of finished fluorspar) was 64,800 tons in 1949, compared with 93,500 tons in 1948. Shipments also were less; they were 63,438 tons—a 25-percent decline from 1948. Of the 1949 shipments, 23,501 tons were shipped by river or river-rail, compared with 21,255 tons in 1948.

Reflecting the inactivity at the Hughett mine, which was an important producer in 1948, output in Caldwell County in 1949 was only 400 short tons, compared with 5,200 tons in 1948.

The major part of the 1949 output in Crittenden County came from the Blue, Commodore, Delhi-Babb, Keystone, Pigmy, Tabb No. 1, and Yandell No. 22 mines. Most of the remainder came from many smaller producing mines, including the Hickory Cane, Holly, Krausse, Mary Belle, Pogue, Reiter, and Watkins; and some was recovered from tailings from previous milling operations.

Production of fluorspar in 1949 by the United States Coal & Coke Co., the largest producer in Kentucky, was virtually the same as in

[4] Needham, A. B., Methods and Costs of Mining Fluorspar from a Flat-Bedded Deposit at Cave in Rock, Ill.: Bureau of Mines Inf. Circ. 7514, 1949, 10 pp.

[5] Bishop, O. M., and Needham, A. B., Investigation of Douglas Fluorite Property, Pope County, Ill.: Bureau of Mines Rept. of Investigations 4424, 1949, 13 pp.

1948, but shipments were 16 percent larger. Output came from the Tabb No. 1 and Yandell No. 22 mines.

The Kentucky Fluor Spar Co. and affiliates shipped 13 percent less fluorspar and "fluorbarite" than in 1948. The company operates a mill at Marion and, through its mining division (Roberts & Frazer), operated the Carr and Wright mines in Livingston County. Only about one-third of the supply came from company mines in 1949; most of it was supplied by the Austin, Blue, Empire, Knox, Krausse, Lead Hill, and Redd mines and the flotation mills of Crider Bros. Fluorspar Co. and Minerva Oil Co.

The Keystone mine and heavy-medium mill of Inland Steel Co. were operated throughout 1949. Output of ore at the Keystone mine was 32 percent less than in 1948, and production at its heavy-medium mill was 30 percent smaller. However, shipments of fluorspar by Inland Steel Co. were 8 percent greater than in 1948.

Output of fluorspar at the Pigmy mine of the Pigmy Corp. (subsidiary of the Rosiclare Lead & Fluorspar Mining Co.) declined for the fifth consecutive year and was 38 percent less in 1949 than in 1948. Much development was in progress at the Pigmy mine in 1949.

Except for a small quantity of fluorspar produced at the Hickory Cane mine, virtually all of the supply of Delhi Fluorspar Corp. in 1949 was purchased from local producers and from Mexico; the Mexican fluorspar was blended with domestic fluorspar. The domestic fluorspar came chiefly from the Austin, Douglas, Knox, and Redd mines in Illinois. The Mexican fluorspar so blended and shipped has not been included in the statistics for Kentucky. Total shipments by Delhi Fluorspar Corp. were 35 percent less than in 1948. The company completed a barge-loading station equipped with a conveyor 62 feet long on the Kentucky side of the Ohio River opposite Cave in Rock, Ill.

L. Conyer shipped 73 percent less fluorspar in 1949 than in 1948. He operates a jig mill near Marion and depends on purchases of local ore and tailings for his supply. Most of it was obtained from the Baker, Redd, and Twitchell mines in Illinois and the Mary Belle mine in Kentucky.

Ben E. Clement, who also depends on purchased fluorspar from local mines and Mexico, sold 74 percent less fluorspar than in 1948. The Mexican fluorspar, which was used to raise the grade of locally purchased fluorspar, has not been included in the statistics for Kentucky.

Crider Bros. Fluorspar Co. worked the Blue mine near Mexico, Ky., reclaimed some fluorspar from the Haffaw and Blue dumps, and purchased fluorspar from local producers. The ore from the company mines is mill feed for its gravity-concentrating and flotation mills. Output in 1949 comprised 65 percent metallurgical-grade fluorspar and 35 percent flotation concentrates. Sales of fluorspar by the company were 50 percent smaller than in 1948.

The C & L Fluorspar Co. operated its flotation mill at Marion, but output of flotation concentrates was 28 percent less than in 1948. The mill feed comprised tailings from local mines. The company purchased much fluorspar from local mines which it blended with its flotation concentrates. Total sales were 60 percent less than in 1948.

The company Hughett mine in Caldwell County did not produce any fluorspar in 1949.

Davenport Mines, Inc., did not operate its Davenport and Hicks mines in 1949 because of installing electric pumps, hoists, and compressors. Meanwhile, however, its heavy-medium mill was operated on ore purchased locally and on ore recovered from dumps that had accumulated for many years.

The Alcoa Mining Co. did not operate any fluorspar mines in Kentucky in 1949, but its Mary Belle mine was leased to and operated by F. B. Moodie, Jr. However, the company did prospect core drilling on the Blue & Marble, Catiller "A" and "B," Gardner-Edmonds, Klondike, Trabue-Skelton, and Wadley properties, and as a result it purchased the Klondike in Livingston County and the Blue & Marble in Crittenden County. Fluorspar and zinc were discovered by diamond drilling on the company-owned Trabue-Skelton property.

In Livingston County, production of finished fluorspar declined to 7,500 tons in 1949 from 9,800 tons in 1948. The output in 1949 came chiefly from the Carr, May, and Mineral Ridge mines and from reworking the Klondike tailings.

Output at the Carr and Wright mines of Roberts & Frazer was virtually the same in 1949 as in 1948.

The Mineral Ridge mine, operated by Alco Lead Corp., produced 22 percent less ore in 1949 than in 1948; its output was shipped to the flotation mill at Rosiclare, Ill., of Ozark-Mahoning Co.

Butler & Moodie continued to reclaim fluorspar from Klondike tailings at its flotation mill near Mullikin.

A report [6] on the Klondike mine has been published.

In the Central Kentucky district, Hageman Properties, Inc., discontinued mining of fluorspar in April, and as a consequence production and shipments declined substantially in 1949. Most of the ore produced in 1949 was shipped to Marion, Ky., where it was treated in the heavy-medium mill of Kentucky Fluor Spar Co.

Montana.—Production of fluorspar in Montana was 422 short tons in 1949, compared with 318 tons in 1948. The output in both years came from the property of Coeur d'Alene Extension Mines, Inc., in Mineral County near Superior. The Riverside Copper Mining Co., Wallace, Idaho, subleased a group of mining claims in this area.

Nevada.—Shipments of fluorspar from Nevada were 5,847 short tons in 1949, a decline of 39 percent from the record year 1948 and the smallest since 1940. Most of the 1949 output went to steel plants; but some was shipped to cement, ferro-alloy, glass, and enamel plants and iron foundries, and a little was exported. The fluorspar moving to glass and enamel plants and exported was ground by Industrial Minerals & Chemical Co., West Berkeley, Calif.

The chief producing mine in Nevada in 1949 was the Daisy, in Nye County, operated by J. Irving Crowell, Jr.; its production was 28 percent less than in 1948. The Baxter mine in Mineral County, operated by V. S. Baxter, was the second-largest producing mine in Nevada in 1949; its output, however, declined 63 percent from 1948. Three cars of fluorspar were produced at the Cirac Revenue Group in Churchill County by C. P. Cirac in 1949.

---

[6] Swanson, A. S., Investigation of the Klondike Fluorspar Deposit, Livingston County, Ky.: Bureau of Mines Rept. of Investigations 4603, 1949, 19 pp.

New Mexico.—Production of finished fluorspar in New Mexico was 13,000 short tons in 1949, a decline of 48 percent from 1948. In addition, about 15,000 tons of crude ore equivalent to 7,800 tons of finished fluorspar was mined but not milled in 1949. Thus, total mine production (expressed in terms of finished fluorspar) was 20,800 tons in 1949, compared with 18,700 tons in 1948. The 1949 output came from Dona Ana, Grant, Lincoln, Luna, Rio Arriba, Sierra, and Valencia Counties. The Zuñi mines in Valencia County, Purple Heart and Shrine mines in Grant County, and Greenleaf and White Eagle mines in Luna County supplied about 67 percent of the fluorspar produced in New Mexico in 1949. Most of the remainder came from many mines and prospects and from tailings from previous milling operations.

Shipments of fluorspar from New Mexico totaled 12,844 tons in 1949, a loss of 49 percent from 1948. The 1949 shipments were the smallest since 1940.

The flotation mill of General Chemical Division, Allied Chemical & Dye Corp., at Deming, produced 13 percent less concentrates in 1949 than in 1948. The mill feed comprised ore from the company-operated Shrine mine in Grant County, purchased ore from local mines—chiefly the Greenleaf and White Eagle mines in Luna County and the Purple Heart mine in Grant County—and tailings from the Gila mill.

The flotation mill of Zuñi Milling Co., at Los Lunas, produced 78 percent less concentrates than in 1948. The mill feed comprised ore chiefly from the company mines near Grants in Valencia County, but a comparatively small quantity of ore was purchased from local mines. Two inclined shafts—one equipped with a skip and a hoist and the other with a belt conveyor—have been completed at the company No. 21 mine.

H. E. McCray operated the Greenleaf and Greenleaf No. 2 mines in Luna County near Deming and purchased fluorspar from the Gratton, Greenspar, Nakaye, and Valley properties in 1949.

Work was continued at the Burro Chief fluorspar property near Tyrone, Grant County, by Phelps Dodge Corp. to determine the possibility of resumption by the corporation of operations formerly carried on by leasers. According to the corporation, the results are inconclusive though not without some promise.

Tennessee.—According to the Tennessee Valley Authority:[7]

A plant-scale demonstration unit for the recovery of fluorine, which is liberated in one form or another in most phosphate-manufacturing processes, was placed in operation at the fused tricalcium phosphate plant toward the end of the year. The process, a relatively simple one in which waste gases from the furnaces are passed through a tower packed with lump limestone, was tested in pilot-plant operation last year. The fluorine is recovered as calcium fluoride, which promises to be a salable byproduct in view of the expanded demand for fluorine compounds.

Charles H. Young, Director, Division of Chemical Engineering, Tennessee Valley Authority, states:[8]

Since the byproduct calcium fluoride produced by the Tennessee Valley Authority thus far has been incidental to the development of the fused tricalcium phosphate fertilizer process, the quality of the byproduct has been erratic. For this reason, the amounts produced have been discarded. Present indications are

[7] Annual Report of the Tennessee Valley Authority for the fiscal year ended June 30, 1949, p. [illegible].
[8] Letter to Bureau of Mines, Mar. 28, 1950.

that the grade of the byproduct will soon become stabilized within the range 80 to 85 percent CaF_2, at which time we propose to undertake the sale of the byproduct.

Texas.—Production of finished fluorspar in Texas was 1,838 short tons in 1949, a gain of 128 percent over 1948; shipments (1,770 tons) were 95 percent larger. Production was from the Eagle Mountains mine in Hudspeth County near Van Horn, operated by the Texas Fluorspar Mines, Inc. Production was suspended during August and September because of a strike at a consumer's plant. A new 600-foot water well with substantial flow was brought in during the first quarter of 1949, thus relieving water shortage for milling. The principal production of ore was from mine No. 4, where sinking to a new working level was in progress at the year end. Preliminary work was going forward at the Fox mine, which will provide a good crude-ore source for 1950.

Utah.—Production of fluorspar in Utah was 8,372 short tons in 1949, a decline of 12 percent from the record high in 1948. However, output in 1949 was the second highest. The bulk of the production came from Juab County near Delta, where George Spor & Sons, Chesley & Black, Willden Bros., and Ward Leasing Co. operated intermittently. All of the fluorspar produced was shipped to the steel plant at Geneva. A car of fluorspar was shipped from a property in Beaver County by Fred Staats, and a car was also shipped from a property in Piute County by Bullion Monarch Mining Co.

MILLING

Output of flotation concentrates from domestic ore totaled 111,247 short tons in 1949, compared with 156,246 tons in 1948. In addition, 33 tons of flotation concentrates were recovered from milling 43 tons of Mexican ore at a plant in the United States.

The Crystal Fluorspar Co., Elizabethtown, Ill., completed a heavy-medium separation mill with a seven-foot cone at its Crystal mine to serve it and its Jefferson mine; the new plant began operating August 8. The new mill replaces a jig plant, which was dismantled.

The Texas Fluorspar Mines, Inc., Van Horn, Tex., added a 5-foot by 4-foot ball mill to its flotation plant, which was overhauled.

Fluorspar, Inc., Salida, Colo., was building a new flotation mill to serve its Aksarben mine.

Two-stage ball milling and triple classification were placed in operation in December in the flotation plant of Minerva Oil Co., Cave in Rock, Ill.

A new ball mill and ore-feeding equipment were added to the milling plant of Rosiclare Lead & Fluorspar Mining Co., Rosiclare, Ill.

Additional equipment was installed in the Rosiclare flotation mill of Ozark-Mahoning Co. to regrind and rehandle middlings from the fluorspar circuits.

The Inland Steel Co. installed a primary crusher and conveyor at its heavy-medium mill near Marion, Ky.

Davenport Mines, Inc., installed a finishing screen in its heavy-medium mill, which will double the head feed.

At its Rolla (Mo.) Branch the Bureau of Mines investigated the pelletization of fine metallurgical-grade fluorspar with various binders.

PRICES

Metallurgical-grade fluorspar containing 70 percent or more effective calcium fluoride content was quoted at $37 a short ton f. o. b. Illinois-Kentucky mines throughout 1949; this price has been in effect since Oct. 14, 1948. The quoted prices on other metallurgical grades of fluorspar remained unchanged at $36, $35, and $34 a ton. Effective January 1, 1949, the selling price of acid-grade fluorspar containing a minimum of 97 percent calcium fluoride was advanced to $45 a short ton f. o. b. Illinois mines; but on September 1 it was lowered to $43.50 a ton.

The average selling price of all grades of domestic fluorspar shipped in 1949 was $34.92 a short ton—a new peak—compared with $33.84 in 1948.

FOREIGN TRADE [9]

Imports.—Receipts of imported fluorspar into the United States were 95,619 short tons in 1949, a loss of 14 percent from the all-time high of 1948. Imports of fluorspar in 1949, however, were the third largest.

Fluorspar imported for consumption in the United States, which represents the quantity on which the duty was paid, likewise declined in 1949; they were also 95,619 tons, or 14 percent smaller than in 1948. The imports in 1949 comprised 20,490 tons containing more than 97 percent calcium fluoride and 75,129 tons of lower grade. They were valued [10] at $1,549,044. The value assigned to the higher-grade fluorspar averaged $24.07 a ton in 1949 and that to the lower grade

[9] Figures on imports and exports (unless otherwise indicated) compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

[10] As defined in sec. 402 of the Tariff Act of 1930: "The value of imported merchandise * * * is the foreign value or the export value, whichever is higher—that is, the market value or the price at which the merchandise, at the time of exportation to the United States, is offered for sale in the principal markets of the country from which exported, including the cost of containers or coverings and all expenses (including any export tax) incident to placing the [illegible] in condition ready for shipment to the United States."

$14.05. The cost to consumers in the United States also includes duty, loading charges, insurance, consular fee, and freight to consuming plants. The duty on fluorspar containing not more than 97 percent calcium fluoride continued at $5.625 a short ton and on fluorspar containing more than 97 percent calcium fluoride $3.75.

In 1949, 3,478 tons of Mexican fluorspar were blended with fluxing-gravel fluorspar from the Illinois-Kentucky district. The Mexican fluorspar so blended has been excluded from the statistics on shipments from mines in the United States and included in the figures on imports.

The following table, compiled from data supplied to the Bureau of Mines by importers and domestic companies milling foreign fluorspar, shows the quantities of imported fluorspar delivered to consumers in the United States in 1948 and 1949, irrespective of year of importation into the United States. The quantities are based upon the actual outturn weights and include the finished fluorspar recovered from milling and drying foreign ore, rather than the ore milled or concentrate dried.

Imported fluorspar delivered to consumers in the United States, 1948–49, by uses

Use	1948			1949		
	Short tons	Selling price at tidewater, border, or f. o. b. mill in the United States, including duty		Short tons	Selling price at tidewater, border, or f. o. b. mill in the United States, including duty	
		Total	Average		Total	Average

Total	111,231	3,013,957	27.10	89,859	2,579,527	28.71

Exports.—Producers of fluorspar reported exports of 783 short tons of fluorspar valued at $32,521 in 1949, compared with 644 tons valued at $24,819 in 1948. The exports (all ceramic ground and flotation concentrates) by producers in 1949 comprised 753 tons to Canada, 20 tons to Pakistan, and 10 tons to Venezuela. In addition to the fluorspar exported by producers in 1949, dealers exported 12 tons to Brazil, 5 tons to Peru, 1 ton to Ecuador, 1 ton to Switzerland, and 1,100 pounds to Bolivia.

Fluorspar reported by producers as exported from the United States, 1944–49

Year	Short tons	Value		Year	Short tons	Value	
		Total	Average			Total	Average
1944	1,980	$65,900	$33.29	1947	1,180	$43,679	$37.02
1945	1,420	45,929	32.35	1948	644	24,819	38.54
1946	1,728	63,797	36.92	1949	783	32,521	41.53

WORLD REVIEW

The accompanying table shows world production of fluorspar, by countries, 1943–49, insofar as statistics are available.

Australia.—The principal fluorspar-producing centers in Queensland are Fluorspar Siding, Mungana, Muldiva, and Alma Den.[11] Production has ranged from 361 to 887 metric tons during the 5-years 1945–49.

World production of fluorspar, by countries, 1943–49, in metric tons

[1] In addition to countries listed, China and U. S. S. R. produce fluorspar, but data of output are not available; estimates by author of chapter included in total.
[2] Data not available; estimates by author of chapter included in total.
[3] Estimate.
[4] Exports to Japan.

Canada.—According to the Dominion Bureau of Statistics, production of fluorspar in Ontario was 5,795 metric tons[12] in 1949, compared with 10,287 tons in 1948. According to information furnished to the U. S. Bureau of Mines by the two producers of fluorspar in Newfoundland, shipments were 50,417 metric tons in 1949, compared with 47,833 tons in 1948.

The St. Lawrence Corp. of Newfoundland, Ltd., has a gravity-concentrating mill and a flotation mill in Newfoundland for treating the ore from its several mines; and a subsidiary, St. Lawrence Fluorspar, Inc., has a plant at Wilmington, Del., for drying the flotation concentrate. Shipments by the St. Lawrence Corp. of Newfoundland, Ltd., and St. Lawrence Fluorspar, Inc., totaled 19,779 metric tons in 1949 (16,963 tons in 1948) and comprised 8,007 tons of fluxing gravel,

[11] Chemical Engineering and Mining Review (Melbourne), vol. 42, No. 1, Oct. 10, 1949, p. 17.
[12] 1 metric ton is equivalent to 1.10231 short tons.

1,574 tons of acid lump, and 10,198 tons of acid-grade flotation concentrate.

Newfoundland Fluorspar, Ltd., has two mines and ships crushed fluorspar principally to Arvida, Quebec, where the Aluminum Co. of Canada, Ltd., has a flotation plant. Shipments were 30,638 metric tons in 1949 (30,870 tons in 1948) and comprised 28,181 tons to Arvida and 2,457 tons to other customers. All of its 1949 production came from the 250-foot level of the Director mine, which was active throughout the year and where development continued. Its Tarefare mine was inactive throughout 1949.

Mexico.—Chiefly as a result of lessened demand in the United States—the principal market for Mexican fluorspar—production (as measured by exports) in Mexico was about 56,000 metric tons in 1949, a decrease of 26 percent from the record established in 1948. About 2,200 tons of Mexican fluorspar are used in local metallurgical plants, and some is exported to Canada.

Southern Rhodesia.[13]—Fluorspar has been mined on a small scale in the Wankie District, Southern Rhodesia, since 1938 and shipped to the steel plant of Bulawayo.

South-West Africa.—According to Chemical Age:[14]

> Important mining developments are taking place in the Otjiwarongo district of South-West Africa on behalf of the iron and steel corporation in Pretoria, Iscor. At Marburg Mountains there is an extremely large deposit of low-grade fluorspar which Iscor intends developing. The deposit, known for a long time, has hitherto not been economically workable. Iscor, however, will be able to use certain grades satisfactorily as a flux in steel processing. There is no immediate market for export fluorspar of these grades, but current investigations suggest that an export market may be secured.

During 1948, the Tsumeb Corp., in which the Newmont Mining Corp., New York, holds a 28½-percent interest, did geologic mapping, trenching, and diamond drilling on company claims at Okurusu, 90 miles southwest of Tsumeb. A description of the deposit was given in the chapter of this series for 1948 (pp. 543–544).

Spain.—Previous to World War II, Spain was a relatively small producer of fluorspar.. During the 27 years 1913–39 its average annual production was only about 3,800 metric tons. During World War II, however, chiefly as a result of demand by Germany and preclusive buying by the United States, production increased phenomenally from 9,097 tons in 1940 to a new high of 55,595 tons in 1944. The defeat of Germany and discontinuance of preclusive buying by the United States resulted in a spectacular drop in production to 8,712 tons in 1946. Since 1946, however, there has been renewed stimulation of development and production, and as a consequence output had increased to 61,915 tons in 1949. Inasmuch as consumption of fluorspar in Spain is small, the industry is largely dependent on the export market for its survival.

The chief producing mines in Spain are the Osor in the Gerona district, the Collada and Obdulia in the Asturias district, and the Fuenteovejuna in Cordoba Province. The Spanish fluorspar is relatively high grade, and simple washing and hand cobbing is generally ample to make metallurgical grade. The Osor mine is served by a flotation mill, which produces ceramic and acid grades of fluorspar.

[14] Chemical Age (London), vol. 62, No. 1593, Jan. 21, 1950, p. 141.

Union of South Africa.[15]—Expansion of the steel industry in South Africa has resulted in greatly increased demand for local fluorspar and, consequently, virtually all production is now consumed in the Union, and exports are small. Virtually all output has come from Transvaal. Deposits in the Zeerust area were worked first in 1918, and peak output, all exported, of 10,975 metric tons was reached in 1923. Western Transvaal continued to be the major producer until 1936, when large deposits in Waterberg district began to be worked. Reserves in the Union have been estimated at 750,000 tons, most of which can be mined by open-pit methods.

United Kingdom.—The United Kingdom has shown much enterprise during and since World War II in developing its fluorspar industry and, as a result, output advanced from an average of 31,000 metric tons during the 10 years 1930–39 to 49,269 tons during the 9 years 1940–48; it reached a peak of 71,124 tons in 1948. Derbyshire and Durham are the chief producing centers.

According to the Mining Journal:[16]

> Present production is from old lead mines reopened for fluorspar working and from dumps. It is estimated that the United Kingdom reserves now amount to some 15 years' supply at a consumption rate of 65,000 tons. However, the recent introduction of flotation in dressing operations is a favorable factor.

CRYOLITE

Cryolite occurs in commercial quantity and is mined at only one place—Ivigtut, Greenland.

Synthetic cryolite was manufactured in the United States in 1949 by the Aluminum Ore Co. at East St. Louis, Illinois, and the Reynolds Metals Co. at Bauxite (Hurricane Creek), Arkansas.

The following information on cryolite is quoted from Industrial Minerals and Rocks:[17]

> At Ivigtut the cryolite ore is associated with pegmatite within an intrusive mass of porphyritic granite. It lies on the shore of Arsuk Fjord, conveniently situated for mining and shipping the product. The mine is worked from slopes leading from the bottom of an open quarry about 500 ft. long, 300 to 600 ft. wide and 150 ft. deep.
>
> The mine is owned by the Danish State and the mining concession by the Kryolitselskabet Oresund A/D, Copenhagen. The crude ore output is normally divided about equally between the Pennsylvania Salt Manufacturing Co., of Philadelphia, and the Danish company's manufacturing plant in Copenhagen.
>
> The crude ore, as mined and containing silica, fluorspar, galena, pyrite, siderite and host rock gangue, is shipped as is to the Pennsylvania Salt Manufacturing Company's processing plant near Pittsburgh, where it is converted into various manufactured products. Prior to 1935, separation of the ore was mainly effected by gravity, but since that time flotation and other mineral-dressing techniques have been employed to better meet rigid product specifications.
>
> The flotation concentrate is a finely divided white powder typically containing 99.4 pct. natural cryolite. The principal use for this product is in the aluminum industry, where it acts as the electrolyte in reducing alumina to the metal. Artificial cryolite made from fluorspar is used extensively for the same purpose but it has the disadvantage of liberating fluorine-containing gases more readily than the natural product when electrolysis is started, thus causing undesirable working conditions. In the aluminum industry, iron and silica are undesirable impurities.

[16] Mining Journal (London), vol. 233, No. 5951, Sept. 10, 1949, p. 532.

[17] Mudd, Henry T., Fluorspar and Cryolite: Industrial Minerals and Rocks, Am. Inst. Min. and Met. Eng., New York, 1949, pp. 396–401, 403.

A high-quality cryolite product is used in the enamel and glass industry. It gives whiteness to enamel and is an opacifier in glass. Here contamination with iron impurities in any form is to be avoided.

Small tonnages are used as a binder for some abrasives and also as insulating material having special dielectric properties.

Some flotation middlings are mixed with rough-dressed ore and then dry-ground to an extremely fine powder, all below 5 microns in size and containing 90 pct. natural cryolite. This product is further processed in various ways and is used exclusively as an insecticide. Natural cryolite, the active ingredient, may be applied to most crops without fear of "burning" and consequent injury to plants. The product usually is mixed with other selective insecticides and wetting or dispersing agents. All such products are proprietary compounds of the Pennsylvania Salt Manufacturing Co. Gangue impurities in these grades merely act as diluents.

Imports of cryolite into the United States were 18,309 long tons valued at $1,312,260 in 1949, compared with 2,101 tons valued at $210,050 in 1948. The cryolite imported in both years came from Greenland.

Exports of cryolite from the United States were 324 long tons valued at $77,709 in 1949, compared with 637 tons valued at $139,027 in 1948. Of the 1949 exports, 130 tons went to Canada, 70 tons to China (Formosa), 53 tons to Mexico, 45 tons to Palestine and Israel, and 26 tons elsewhere.

Fuel Briquets and Packaged Fuel[1]

By J. A. Corgan and Golden V. Chiriaco

GENERAL SUMMARY

CONSISTENT with the general downward trend in the output of solid fuels, there was a sharp decline in the production of both fuel briquets and packaged fuel in 1949, when fuel briquets totaled 2,403,971 net tons, the lowest output since 1943, and packaged fuel 125,948 tons, the lowest annual production since 1936. Briquets were shipped to 37 States and the District of Columbia in 1949. Exports, virtually all destined for Canada, totaled 167,140 tons, and imports, all from Canada, totaled only 365 tons.

Bituminous coal and Pennsylvania anthracite were the principal raw fuels used in the manufacture of fuel briquets and packaged fuel in 1949; asphalt binders were used almost exclusively in making briquets, and both asphalt and starch, together with a small amount of cement, were employed as binders in manufacturing packaged fuel.

FUEL BRIQUETS

Pertinent data on the fuel-briquetting industry from 1945 to 1949 are summarized in table 1. As indicated in this table, the 1949 output is still more than double the average production during the period 1935–39. Production, by regions, from 1917 to 1949 is illustrated in figure 1.

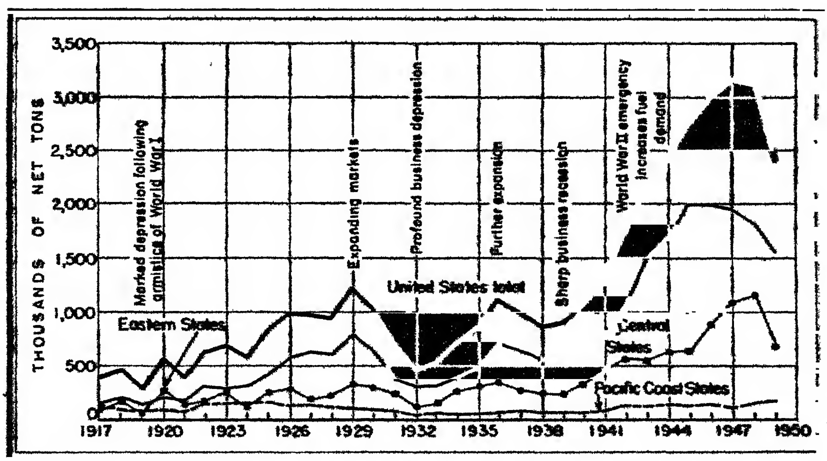

FIGURE 1.—Production of fuel briquets in the United States, by regions, 1917–49

[1] Briquets made from charcoal, wood scrap, and fruit pits are not included in Bureau of Mines review.

DOMESTIC PRODUCTION

The decline in the production of fuel briquets from 3,128,477 net tons in 1948 to 2,403,971 in 1949, a 23-percent decrease, can be attributed largely to the unusually mild winters of those years and to competition from other space-heating fuels, especially fuel oil and natural gas. The decrease in production was much more severe in the Eastern States than in the Central States, where briquets are used more extensively than in other areas. The tonnage produced in the Pacific Coast States is not great, and this group of States showed an increase over the 1948 output.

As indicated in table 2, 33 plants[2] produced briquets in 1949. A total of 14 States contributed to the 1949 production, with 22 plants in the Central States accounting for 65 percent of the total output. Wisconsin, with 10 plants and 45 percent of the national output, was the largest individual producing State. Pennsylvania followed with 4 plants, accounting for 14 percent, and West Virginia ranked third with 3 plants operating. Other producing States, in order of output, were as follows: Missouri, Oregon, Illinois, Washington, Arkansas, North Dakota, Kansas, Michigan, California, Nebraska, and Massachusetts. The total value of the 1949 production, $28,641,424, was a decline of 20 percent from the value of $36,011,322 reported in 1948.

[2] Directories of fuel-briquet and packaged-fuel operations and a list of manufacturers of briquetting machinery, M. M. S. 1861, 1862, and 1860, respectively, are obtainable on request from the Bureau of Mines, Washington 25, D. C.

TABLE 2.—Production of fuel briquets in the United States, 1948–49

	1948			1949

Capacity.—Table 3, showing capacity and production for 1945 to 1949 indicates that, since the peak of 73 percent of capacity was attained in 1945, the trend has been downward, and in 1949 the industry worked at only 52 percent of capacity. In 1949, nine plants, each with an annual capacity of 200,000 tons or more, furnished 1,673,831 tons, or 70 percent of the total production, utilizing 54 percent of their combined capacity. It is of interest to note also that 16 plants with 100,000 tons or more annual capacity accounted for 88 percent of the total production in 1949.

TABLE 3.—Annual capacity and production of briquetting plants in the United States, 1945–49

Raw Fuels.—Bituminous coal was the principal raw fuel used in the manufacture of fuel briquets in 1949, followed in order by Pennsylvania anthracite and Arkansas hard coals. These fuels accounted for 89 percent of the raw fuels used. In addition, small amounts of residual carbon from the manufacture of oil gas, residual carbon from pyrolysis of natural gas, lignite char, and petroleum coke were used as raw fuels. Yard screenings used at 14 plants comprised about 20 percent of the raw fuels used in the manufacture of briquets in 1949. Pennsylvania anthracite was used extensively, either alone or in combination with bituminous coal, in Pennsylvania and Wisconsin. Bituminous coal was used widely in the Eastern and Cen-

TABLE 4.—Raw fuels used in making fuel briquets in the United States in 1949

Character of raw fuels used	Plants	Net tons
Pennsylvania anthracite	17	646,645

tral States. Residual carbon from oil gas and natural gas was the principal raw fuel used in the Pacific Coast States.

Binders.—Asphalt binders were used almost exclusively in making briquets in the United States. In 1949, 31 operators used approximately 151,000 tons of asphaltic binders and very small quantities of coal-tar pitch; 2 operators used no binder. The percentage of binder in the briquets (by weight) ranged from less than 5 to 9 percent or more. Twenty-six plants, accounting for about 90 percent of the 1949 production, used binders ranging from 5 to 8 percent of the weight of the briquets.

TABLE 6.—Classification of briquetting plants in the United States by type of binder used, 1946–49

	1946		1947		1948		1949

[1] Residual carbon from manufacture of oil gas and bituminous coal were raw fuels used at plants employing no binder.

SHIPMENTS

Weight and Shape.—In 1949 briquets ranged in weight from 1½ to 20 ounces. Pillow shapes under 5 ounces (except for an 11-ounce bituminous high-volatile pillow) were made at 30 plants and represented 82 percent of the total production; 2½-ounce cylindrical (barrel-shaped) and 18- and 20-ounce cubes supplied 18 percent of the total production.

In addition to the 2,182,671 tons of fuel briquets shipped to 37 States and the District of Columbia in 1949, 167,140 tons were exported to Canada, including a small tonnage to Newfoundland-Labrador. Imports, all from Canada, amounted to 365 tons. As indicated in table 7, Wisconsin, Minnesota, Missouri, and Michigan received 1,275,919 tons of the total briquets shipped in 1949. The difference between production in 1949 (2,403,971 net tons) and shipments within the United States (2,182,671 tons), or 221,300 tons, represents briquets exported, used at plants for power or heat, and changes in producers' stocks. Briquets are used almost entirely for space heating, but in 1949 operators reported 3,923 tons used for power or heat at their plants.

Seventy-seven percent of the total shipments of fuel briquets moved by rail and 23 percent by truck in 1949. In the Eastern States, 96 percent was shipped by rail and 4 percent by truck; in the Central States, 72 percent moved by rail and 28 percent by truck; and in the Pacific Coast States, 47 percent moved by rail and 53 percent by truck.

TABLE 7.—Shipments of fuel briquets of domestic manufacture in the United States, by States of destination, as reported by producers, 1948–49, in net tons [1]

State of destination	1948	1949	State of destination	1948	1949

[1] Includes shipments outside the United States.
[2] Includes small tonnage shipped by scow.
[3] An additional 22,283 tons were used by 4 producers as fuel at their plants in 1948 and 3,923 tons by 3 producers in 1949.

PRICES

As indicated in table 1, the average per ton value of briquets (f. o. b. plant) produced in the Eastern, Central, and Pacific Coast States increased substantially each year during the period 1945–48; however, the increases shown for 1949 over 1948 are in most cases negligible and not nearly so large as those shown for previous years. Sales values received by producers (f. o. b. plant) vary greatly because of the different local conditions under which briquets are made. In the Eastern States, briquets are made relatively near the coal fields where the cost of raw fuel does not involve large freight charges; hence the f. o. b. plant value is relatively low. In the Central States briquets are generally made at plants great distances from the original coal source; consequently, raw fuel at these plants involves a considerable freight charge, which is reflected in higher values per ton f. o. b. plant. The highest plant values are shown in the Pacific Coast States, where

the raw feuls used are residual carbons from the manufacture of oil gas and pyrolysis of natural gas.

These values vary considerably from the prices at which briquets are sold to consumers, as retail prices include transportation costs to market and retail dealers' margins. Retail prices of fuel briquets for certain selected cities may be obtained from the Bureau of Labor Statistics, United States Department of Labor, Washington 25, D. C.

FOREIGN TRADE [3]

Imports of fuel briquets into the United States reached a peak of 123,593 net tons in 1926, when a strike in the Pennsylvania anthracite fields created a shortage of fuels in this country. Imports have been negligible since 1941, amounting to only a few hundred tons a year; and in 1949 only 365 tons, all of which came from Canada, were imported.

In 1949 exports of fuel briquets, all to Canada and Newfoundland-Labrador, totaled 167,140 tons, a decline of 20 percent from 1948. The value of the 1949 exports was $2,438,284, a decrease of 8 percent from 1948.

TECHNOLOGIC DEVELOPMENTS

The recovery, upgrading, and utilization of fine sizes of anthracite have received considerable technological consideration during the past several years, and the Anthracite Institute and the Pennsylvania State College have released a number of reports on pelletization or the briquetting of anthracite fines by extrusion. These reports discuss the machines, binders, and wetting agents used; the properties of the silts briquetted; and the relation of silt composition to the strength and combustion characteristics of the pellets.

Considerable research on the briquetting of various coals has been conducted during the past several years by the Illinois State Geological Survey, the University of Utah, and the University of Wyoming. Detailed data on briquetting of dried low-rank western coals are contained in a report [4] released in 1949 by the University of Wyoming. The report presents the results of a research project designed to provide information to increase the utilization value of low-rank western coals by drying and briquetting. The technical data contained in the report are from laboratory and pilot-plant studies conducted by the university in cooperation with the Bureau of Mines. An interesting conference [5] was held in June 1949 at the University of Wyoming to discuss various coal-briquetting processes and procedures.

The Bureau of Mines compiled a bibliography on briquetting.[6]

WORLD PRODUCTION

Data on the production of fuel briquets in all countries are not available; however, as indicated in table 10, Germany is apparently the world's greatest producer of fuel briquets. Although Germany showed a substantial increase over 1948, a number of other countries showed decreases.

PACKAGED FUEL

Salient statistics of the packaged-fuel industry in the United States from 1945 to 1949 are summarized in table 11. Production, by regions, for 1935–49 is illustrated in figure 2.

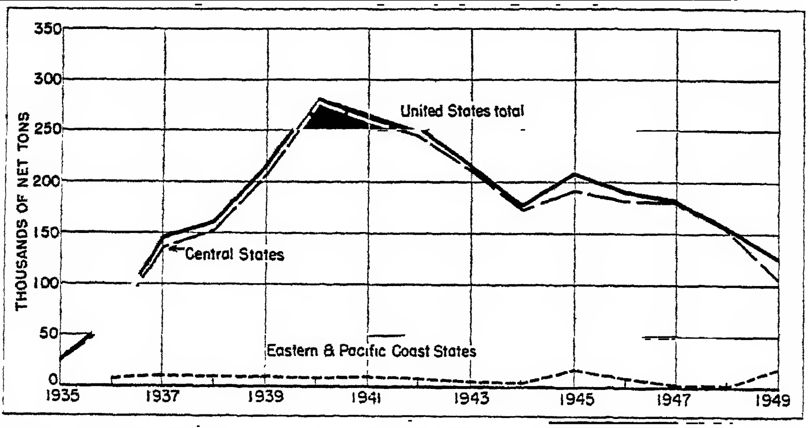

FIGURE 2.—Production of packaged fuel in the United States, by regions, 1935–49. (No production in Pacific Coast States, 1943–49.)

At the 1950 annual convention of the National Association of Packaged Fuel Manufacturers, held in St. Louis in June, there was considerable discussion regarding a new process [7] that has been developed for making packaged fuel by extrusion. The discussion referred particularly to the saving of costly labor in the new process and the density and hardness of the product.

TABLE 11.—Salient statistics of the packaged-fuel industry in the United States, 1935–39 (average), 1940, and 1945–49

[7] National Association of Packaged Fuel Manufacturers, (1801 Gage Blvd., Topeka, Kans.), Sales-Merchandising Bull. vol. 11, No. 8, June 24, 1950, 9 pp.

DOMESTIC PRODUCTION

In 1949, 57 plants operated in the United States, as compared with 62 plants in 1948, and produced 125,948 net tons of packaged fuel valued at $2,236,748, a decrease of 20 percent in tonnage and 18 percent in value from the preceding year. Michigan and Ohio were the two largest producing States in the order named and accounted for about 54 percent of the 1949 output. As indicated in table 11, the average value per net ton (f. o. b. plant) of packaged fuel has increased consistently in both the Eastern and Central States from 1945 to 1949, inclusive; however, the increase per ton shown for 1949 over 1948 is small when compared with the increases indicated for other years. The values received by the manufacturers comprise cost of coal at the mine, freight rates, direct and indirect manufacturing costs, and profit and hence may vary greatly from plant to plant, depending upon local conditions under which the product is manufactured. Production of packaged fuel by States for 1948–49 is shown in table 12.

TABLE 12.—Production of packaged fuel in the United States, 1948–49, by States

State	1948			1949		
	Plants	Net tons	Value	Plants	Net tons	Value
Michigan	22	55,559	$897,647	19	39,254	$660,874
Minnesota	4	17,401	372,507	4	16,197	332,100
Ohio	17	27,776	509,169	17	28,768	516,792
Wisconsin	8	35,143	600,658	7	23,720	402,560
Other States	[1] 11	21,134	355,880	[1] 10	18,009	324,422
Total	62	157,013	2,735,861	57	125,948	2,236,748

[1] Comprises 2 plants each in Illinois, Indiana, and Virginia, and 1 plant each in Iowa, Kentucky, Maine (none in 1949), Missouri, and Nebraska.

Number of Plants.—Of the 57 plants[8] producing packaged fuel in 1949, 19 plants were located in Michigan and accounted for 31 percent of the total output; and 17, located in Ohio, accounted for about 23 percent of the production. Wisconsin was the third-largest producing State.

Capacity of Plants.—Table 13 gives comparative data on capacity and production for 1945–49, inclusive, as reported by packaged-fuel operations active in those years. In 1949, 15 large plants with a capacity of 5,000 tons or more, operating at 39 percent of their combined capacity, produced 88,738 tons of packaged fuel, or 70 percent of the total 1949 output. Forty-two plants, each with an annual capacity under 5,000 tons, produced 37,210 tons or 30 percent of the total production, utilizing 35 percent of their combined capacity.

[8] Work cited in footnote 2.

TABLE 13.—Annual capacity and production of packaged-fuel plants in the United States, 1945–49

	Active plants		Production		
	Number	Annual capacity (net tons)	Net tons	Percent of— Annual capacity	Percent of— Annual production

Total	57	331,300	125,948	38.0	100.0

Raw Fuels.—Five kinds of raw fuels entered into the manufacture of packaged fuel in 1949. Bituminous low-volatile coal at 50 plants, used either alone or in combination with other fuels, comprised 90 percent of the total raw fuels used. Small quantities of bituminous high-volatile coal, Pennsylvania anthracite, semianthracite, and petroleum coke were used also in the manufacture of packaged fuel in 1949. Yard screenings were used exclusively at 27 plants to produce 26 percent of the total output; raw fuels other than yard screenings were used exclusively at 12 plants to manufacture 27 percent; and both screenings and other raw fuels combined were used at 18 plants to produce 47 percent of the total 1949 production.

TABLE 14.—Raw fuels used in making packaged fuel in the United States, 1949

Character of raw fuels used	Plants	Net tons	Plants using—	Plants	Raw fuels used (net tons) Yard screenings	Other raw fuels	Total
Bituminous low-volatile	50	113,027	Yard screenings exclusively (from own or other yards)	27	31,875	-------	31,875
Bituminous high-volatile	5	2,815	Raw fuels (other than yard screenings) exclusively	12	-------	34,319	34,319
Pennsylvania anthracite	1	} 3,689	Both yard screenings and other raw fuels	18	22,107	37,085	59,192
Semianthracite	3						
Petroleum coke	6	5,855					
Total	[1] 57	125,386	Total	57	53,982	71,404	125,386

[1] A number of plants used more than 1 kind of raw fuel; hence, the sum of the plants above is greater than the actual number of plants active (57) in 1949.

Binders.—Starch, totaling 691 tons, or an average of about 14 pounds per ton of packaged fuel produced, is the principal binder employed and was used at 52 plants producing about 78 percent of the total 1949 output. Asphalt, totaling 1,676 tons, or about 127 pounds per ton, was used exclusively at three plants, and cement, in small quantities, about 71 pounds per ton, was also used as a binding agent. Table 15 gives details on binders used in manufacturing packaged fuel for 1946–49.

TABLE 15.—Classification of packaged-fuel plants in the United States by type of binder used, 1946–49

	1946		1947		1948		1949	
	Plants	Percent of total packaged-fuel production	Plants	Percent of total packaged-fuel production	Plants	Percent of total packaged-fuel production	Plants	Percent of total packaged-fuel production
Type of binder used:								
Starch	65	72.7	58	77.9	57	79.8	52	78.3
Asphalt	3	26.0	2		3	19.5	3	20.6
Starch and asphalt	1	1.3	1	22.1	1	.7	1	1.1
Cement	2		2		2		2	
Total	[1] 70	100.0	[1] 62	100.0	[1] 62	100.0	[1] 57	100.0
Production (net tons)		190,919		182,881		157,013		125,948

[1] 1 plant making 2 types of packaged fuel used starch binder for 1 and asphalt and starch for the other; hence the sum of the items shown exceeds the number of active plants.

SHIPMENTS

Sales of packaged fuel in 1949 amounted to 125,948 net tons, of which 108,606 tons (86 percent) were listed as local sales (by truck) and 17,342 tons (about 14 percent), were reported as other than local sales. Of the 17,342 tons shipped outside the local area, 11,036 tons (about 64 percent) went by truck and 6,306 tons (36 percent) by rail.

TABLE 16.—Shipments of packaged fuel in the United States by method of transportation, 1945–49, in net tons

Year	Shipped by truck			Shipped by rail	Total
	Local sales [1]	Other than local sales	Total truck		
1945	171,621	23,381	195,002	11,713	206,715
1946	150,770	25,262	176,032	14,555	190,587
1947	147,599	23,749	171,348	11,270	182,618

1949	108,606	11,036	119,642	6,306	125,948

[1] Includes sales called for and delivered.

Gem Stones

By W. F. Foshag,[1] George Switzer,[1] and G. W. Josephson

THE JEWELRY INDUSTRY IN 1949

AT THE close of 1948 business as a whole in the United States was at its all-time peak. The jewelry volume had declined from its sensational 1947 peak. The traditional seasonal pattern of the jewelry industry reasserted itself for the first time in 10 years. Prices in general began to decline in early 1949, and jewelers liquidated their stocks to establish low inventories. During spring and early summer business was quiet but became active in July and August, when business confidence was restored, and was reasonably so during the fall months; the weeks before Christmas saw the traditional rush for jewelry-store merchandise. High-priced diamond jewelry lagged, however, because of anticipated reduction of present excise taxes. According to a survey made by the National Wholesale Jewelers' Association, diamond sales showed a 19-percent decline in 1949 compared to 1948.

The Jewelers' Circular-Keystone, using United States Department of Commerce statistics and Internal Revenue (excise tax receipts) data, figured that the volume done by jewelry stores in 1949 was approximately $1,055,000,000, a decline of 12 percent from 1948.

FASHIONS IN JEWELS

The fashion aspect of the jewelry industry received more recognition in 1949 than ever before. The Jewelry Industry Council appointed a fashion director and began to include jewelry fashion shows and other forms of jewelry entertainment for the fashion press in its regular schedule of activities. A fashion advisory committee of the Jewelry & Allied Industries was organized to bring together designers, artisans, and promoters in the fields of apparel and jewelry. These organizations deal with costume jewelry as well as with diamonds and other precious jewelry.

The fashion picture as a whole was conservative. Paris made no radical change in styles. However, there was a strong trend in America toward the styles of the 1920's, and the persistence of this trend is slowly affecting the design of jewelry. Bracelets are becoming increasingly popular, as are longer chains and pendants. The most noticeable change in jewelry fashion was the return to pendant earrings. The trend is more and more toward white metals for the

[1] Smithsonian Institution; consulting mineralogist to Bureau of Mines.

mounting of diamonds, but in the more elaborate pieces very little metal was visible. Manufacture was ingenious from the standpoint of mechanical construction. Diamonds were set in hundreds of tiny links, invisibly hinged to form mobile showers of baguettes and "trembling" leaves, stems, and petals. Kite, keystone, and triangle cuts were incorporated into this fine jewelry, and the marquise and pear shape continued to be used.

In diamond engagement-ring mountings the locked-together types of engagement ring and wedding band have become more common. Ingenuity continued to make small diamonds look larger. The demand for straight-sided stones, especially diamond, increased.

DOMESTIC PRODUCTION

For many years the United States has produced a large variety of gem materials but has never been an important factor in world gem production. Gem mining has been and probably will continue to be a minor mining industry.

No large gem-mining companies exist in the United States. A few small companies have been organized from time to time to work certain deposits, such as jade, turquoise, sapphire, and tourmaline. Some professional lapidary shops employ a few miners. In addition, thousands of amateur lapidaries spend their vacations and weekends searching for gem materials, particularly for varieties of quartz (agate, jasper, and petrified wood). Many of their products go to local jewelers or roadside curio shops, particularly in southwestern, western, and northwestern States. As a hobby, the lapidary craft is continuing to spread.

No reliable statistics exist as to the value of the domestic output of gem stones; in the rough it may approximate $400,000 to $500,000 and more than double that after cutting.

The many forms of quartz, chiefly the cryptocrystalline varieties, led the field, with jade second and turquoise third. Of the States, Oregon, Wyoming, Washington, and Texas were the leaders.

Agate.—Agate production, including all other varieties of chalcedony, such as jasper and petrified wood, is increasing as interest in the lapidary craft grows. "Thunder eggs" continued to be produced, chiefly in Oregon. The well-known Yellowstone River moss-agate locality in Montana is still producing but in ever decreasing quantity, with few if any full-time agate hunters.

It is estimated that over 50 tons of agate were produced in New Mexico, plus an additional unknown amount picked up by private collectors. Considerable agate was produced in west Texas, mostly near Alpine, in the Big Bend section, and near Laredo. South Dakota produced some agate, mined by Scott's Rose Quartz Co.

A relatively large amount of agatized wood was collected on the borders of the Petrified Forest National Monument, Ariz. New finds of petrified wood were reported from various localities in Oregon and Washington.

A small amount of chrysoprase was mined at Porterville, Calif.

Red jasper from Vermont was offered in ton lots, mined by the Burlington Gem Co.

Jade.—Allan Branham, Lander, Wyo., stated that the light-green jade (nephrite) in Wyoming is largely depleted but that new finds of dark green and black had been made. The year 1949 was the poorest in the past 13 for Wyoming jade; total sales were approximately $20,000, with the price of light green ranging from $10 to $15 per pound and dark green and black from $5 to $10 per pound.

A large deposit of black jade was found at Kortes Dam, Wyo. A single piece weighing 1,500 pounds was taken out. A newly discovered field at Daniel, Wyo., is reported to be of poor quality.

The American Jade Co., Denver, Colo., reportedly spent over $50,000 developing its jade deposit in the Sweetwater River area, Wyoming.

A new deposit of nephrite jade was discovered on Lewis Hill, 2 miles north of Porterville, Tulare County, Calif.; 1 ton was mined, with several more tons in sight. The jade is reported to vary in color from medium to dark green, with excellent translucency. Operators of the mine are Frank Janolco and F. V. Alston, Porterville.

Some nephrite jade was produced from the Monterey County, Calif., locality, chiefly by amateur collectors.

In November 1949 a deposit of jadeite jade was found on Clear Creek, San Benito County, Calif., by the late L. Ph. Bolander, K. J. Fritsch, and Buck Bleifus. The jadeite mined thus far has been dark green and not of gem quality. Considerable interest is being manifested in this deposit because it represents the first discovery of jadeite jade in the Western Hemisphere other than worked pieces in the tombs of ancient civilizations in Central America.

The Havenstrite Mining Co. (formerly Arctic Circle Exploration Co.) mined no jade in the Kobuk area, northwestern Alaska, during 1949, and reports no known mining by any other organization or individual in the Territory.

Turquoise.—Production of turquoise in the Southwest appears to be steadily diminishing. The Southwest Gem & Jewelry Co. mined 75 to 100 pounds at its Cerebrat ranch, Arizona, property. There was no production reported from New Mexico during the year. Some turquoise is mined in Lander County, Nev.

Diamond.—In October 1948 mining operations in the well-known diamond-bearing kimberlite pipes near Murfreesboro, Ark., were started once again, after a shut-down of many years, by a diamond corporation headed by Glenn L. Martin. Milling was carried on in a washing and recovery mill having a capacity of 1,000 tons a day. Surface-mining methods were used. After 120 thousand tons of various surface ores had been mined from numerous localities in the 60 acres showing peridotite, the enterprise was closed as of September 1949.

The company obtained approximately 840 diamonds, the largest a stone of 4¼ carats. Ninety percent of the stones recovered were small industrials from one-tenth to 1 carat in size. Total diamonds produced weighed 246.15 carats. The indicated yield of the ground treated is 0.16 carat per 100 loads (16 cubic feet), compared with 24 carats per 100 loads for the Premier mine in South Africa. The production consisted of 10 percent very imperfect distorted pieces of mixed color, 5 percent seconds of dark-brown tint, 20 percent small-

size mixed industrials, and 65 percent crushing boart. The appraised valuation was $984.60.

A 3.93-carat diamond was found near Peru, Miami County, Ind., in 1949.

Other Gem Stones.—Utah reported that about the normal amount (300 pounds) of variscite was produced, mostly from the Clay Canyon deposit.

Scott's Rose Quartz Co. mined about 100 pounds of rose quartz in South Dakota. The Bumpus quarry, Albany, Maine, reopened and produced about 50 tons of rose quartz, much of good color, including a single piece weighing 2,000 pounds.

Some transparent light-yellow labradorite was produced in Utah, probably not over 25 pounds in all.

No sapphires were produced at the Yogo sapphire mine, Montana. The mine has been taken over by a new company, the Yogo Sapphire Mining Co. It is reported that the mine will be reopened and worked during 1950.

Arkansas continued to produce some quartz crystals.

A number of good crystals of green tourmaline were produced in the Pala District, San Diego County, Calif., some of which were cut into stones of over 1 carat. Some golden and pale-pink beryl and a very small amount of kunzite were also produced.

A very fine gem-quality green beryl crystal, weighing 14½ ounces, was found in Riverside County, Calif. The exact locality has been withheld pending further exploration by the discoverers.

Other gem stones produced in small amounts in 1949 in the United States follow: Beryl, Mt. Antero, Colo.; amblygonite, beryl, and spodumene, Maine; idocrase ("californite"), Siskiyou County, Calif.; and topaz, Texas and Utah.

CANADIAN GEM STONES

Again in 1949 Canada produced very little in the way of gem stones. A few tons each of sodalite, peristerite, amazonite, and labradorite find their way each year to dealers in Canada and the United States. The annual value of Canada's gem-stone production probably does not exceed a few hundred dollars.

IMPORTS [3]

Imports of gem stones, exclusive of industrial diamonds, in 1949, as reported by the United States Department of Commerce, totaled $84,185,631, about 27 percent less than in 1948. Of the total, diamonds comprised 83 percent.

DIAMOND

World production of diamonds was about 36 percent greater in 1949 than in 1948. Output for the Union of South Africa was approximately the same. The large increase came from the Belgian Congo, where production increased from a little less than 6,000,000 carats to over 9,600,000 carats. Tanganyika continued to show a steady rise.

Sales of rough by the principal distributors (Diamond Trading Co. for gem diamonds and Industrial Distributors (1946), Ltd., for industrial diamonds) were £28,446,000 for 1949 as compared with a little over £38,000,000 in 1948.

Cutting.—The number of employed cutters fluctuated throughout 1949 with the course of business, and there was considerable unemployment. The cost of cutting in the United States continues substantially higher than in other diamond-cutting centers of the world. Half the cutters are Belgians. Conditions in the Netherlands' cutting industry were fairly satisfactory, with about 1,500 to 1,600 workers employed. The Israel diamond-cutting industry was beset by many problems, chiefly lack of supply of rough from the Diamond Syndicate. Cutting in Germany caused other diamond-cutting centers considerable difficulty. An effort is being made to revive the diamond-cutting industry in Cuba.

Imports.—Imports of gem-grade diamonds into the United States decreased from $100,645,415 (revised figure) in 1948 to $69,727,517 in 1949, a decrease of 31 percent. The dollar value of both rough and cut decreased, as did the quantity of both. Belgium furnished 47 percent (value) of the cut in 1949.

[1] Revised figure.

World Production.—Official figures on diamond production are not available for all countries, but the figures in the accompanying table are believed to be reasonably accurate as they have been compiled from Government reports, information supplied by officials of producing companies, and other authoritative sources. World production (gems and industrials) is estimated to have been 13,635,000 carats (3.01 short tons), which compares with 10,047,000 carats (2.21 short tons) for 1948, an increase for 1949 over 1948 of 36 percent.

Belgian Congo was the leading producer by weight but not by value since only about 7 percent of the Belgian Congo production is of gem quality. South Africa, on the other hand, although producing much less by weight led in terms of value.

Industrial Diamonds.—Sales of industrial diamonds in 1949 were very large, although considerably less than in 1948. Total sales in 1949 by Industrial Distributors (1946), Ltd., the industrial-diamond sales organization for the DeBeers group, were valued at £8,469,811. The United States purchased a large percentage of the total quantity, both for private industry and for the National Stockpile.

World production of diamonds, by countries, 1946–49, in metric carats

[1] Exports.
[2] Estimated.
[3] Includes an estimate of 100,000 carats for State Mines of Namaqualand.

The use of diamond drills for exploring and breaking ore is expanding, and the use of diamond-impregnated wheels is increasing. The only significant new use of industrial diamonds is for drilling in oil fields. Bits up to 12 inches in diameter have been used, although the common sizes are 6- and 8-inch. These bits are being used not for core recovery but for "making hole."

Figure 1 shows the increase in the quantity of industrial diamonds imported into the United States in the past 27 years, as contrasted with the price per carat.

[1] Revised figures.

RUBY, SAPPHIRE, AND EMERALD

The precious stones, other than diamond, continued to increase in price owing to short supply of newly mined stones of fine quality.

A 2-ounce particolored sapphire was reported found along the bed of a gully near Tomahawk Creek, Central Queensland, Australia, a locality where gems had not been previously known to exist.

A star sapphire was found in a mine in the Ratnapura District, Ceylon, weighing nearly one-half pound. It is believed that two stones of about 400 carats each can be cut from it.

Mining has been resumed at the famous Chivor-Somondoco mines in Colombia according to reports. The old "terrace" type of mining has given way to conventional underground methods.[3] Production for 1949 was reported to be 91,656 carats compared with 82,370 carats for 1948.[4]

The emerald mines at Muzo, Colombia, have been closed by the Banco de la Republica, after operating for the year at a considerable loss.

Emeralds were mined in India, at Kaliguman, a small village in the Udaipur district in the State of Rajasthan. A small proportion of the production reportedly yielded stones of fine quality. Production of all qualities for 1948–49 was approximately 15,000 carats.

South Africa and Brazil continue to produce a few emeralds.

[3] Bureau of Mines, Mineral Trade Notes: Vol. 30, No. 1, January 1950, pp. 29–38.
[4] Bureau of Mines, Mineral Trade Notes: Vol. 31, No. 1, July 1950, pp. 31–32.

Ceylon produces not only ruby and sapphire but also alexandrite, cat's-eye, and a variety of less valuable gem stones. Most of these are recovered from gravels by placer mining. An estimated half million dollars' worth of gems is produced each year.

LESSER GEMS

The Australian opal-mining industry continues at a low ebb. Only about 100 miners are active. The once famous black-opal fields at Lightning Ridge, New South Wales, are almost exhausted.

Brazil continued to produce a large caratage of the lesser gems, principally amethyst, aquamarine, citrine quartz, and topaz.

TECHNOLOGY

Synthetic rutile (titania) was made in quantity by the Linde Air Products Co. and the National Lead Co. The material is grown in boules by a modification of the well-known Verneuil technique. No completely colorless material has been made, the nearest to this being tinged with yellow. Other shades such as red, blue, green, brown, and yellow have also been made. The refractive index of synthetic rutile is considerably higher than diamond, while its dispersion is approximately three times that of diamond.

Several experiments were reported in which the color of topaz, sapphire, and other gems was changed by exposure to radium radiation. The turning of yellow diamonds green and colorless quartz purple by bombardment in a cyclotron was also reported.

Education and Laboratories.—The Gem Trade Laboratory of New York consolidated with the Gemological Institute of America, the new laboratory to be known as the Gem Trade Laboratory of the Gemological Institute of America, 5 East Forty-seventh Street, New York, N. Y.

The Diamond Research Laboratory of Johannesburg, Union of South Africa, was established recently by the leading diamond companies of the world for two purposes: (1) To assist the mining companies in problems concerning their extraction processes and in investigations leading to increased output and reduced cost and (2) to act as a research and service center for all who use diamonds in any form.

Gold and Silver

By Charles White Merrill and Helena M. Meyer

GENERAL SUMMARY

UNITED States mine production of gold in 1949 decreased 1 percent compared with 1948, continuing the downtrend from the postwar high established in 1947. The 1949 output was twice the wartime low reached in 1945 but was smaller than in any prewar year since 1895. Silver production also decreased, the 1949 output being 9 percent below that for 1948. The gold-mining industry had returned to unrestricted operations when War Production Board Order L–208 was rescinded, effective July 1, 1945; but many mines producing in prewar years did not resume work or did so on a restricted scale only. Higher prices for equipment and supplies and higher wages made former operators reluctant to reopen mines with narrow prewar profit margins. Continued inflation, with little evidence that inflationary forces soon would be arrested, discouraged those who might otherwise have promoted new gold-producing enterprises. Moreover, in many instances the years of idleness had resulted in deterioration of plants and mine workings, which required very large capital outlays for rehabilitation.

The reversal in 1949 of the postwar uptrend in silver production is explained largely by the recession in copper, lead, and zinc prices accompanied by curtailed output at mines producing these metals and byproduct silver. The higher Treasury buying price for silver domestically mined after July 1, 1946, continued to encourage silver mining.

California, which had been the leading gold producer since 1946 was forced into second place in 1949 by South Dakota, where output expanded 23 percent compared with 1948. These two States, plus Utah and Alaska in third and fourth places, respectively, supplied 72 percent of the United States total output. South Dakota output came almost entirely from gold ore produced at the Homestake mine, California production came principally from straight gold mines (both placer and lode), Utah production was mainly a byproduct from the treatment of copper ore mined in the West Mountain (Bingham) district, and Alaska gold was almost entirely from placers and was mostly recovered by bucket-line dredges. Idaho continued to be the leading silver producer, followed in importance by Utah and Montana, an order unchanged since 1943. These three States supplied 67 percent of the 1949 domestic output. About half of the Idaho production was recovered from dry ores, but most of the rest from the three States was a byproduct of ores treated principally for base metals.

Gold produced in 1949 was divided fairly evenly among that recovered at amalgamation-cyanidation mills, that recovered by the smelting of crude ores and concentrates (only a very small part of which was recovered by direct smelting of ore), and that saved by placer methods. Almost 87 percent of the domestic silver output was

943785—51——36

recovered by smelting concentrates and nearly all of the remainder by the direct smelting of ore.

Outside the United States, gold production rose about 5 percent. The slight over-all gain cannot be credited, as would be expected, to devaluation of currencies in many countries, because total production following devaluation in September was no greater than in several preceding months. Devaluation did tend to increase output in certain areas and doubtless will cause further gains in 1950; but the fact that some companies with limited hoisting or milling capacity, in terms of tonnage, grasped the opportunity to treat ores having a lower average gold content was a counterbalancing factor. World production of silver in 1949 was 4 percent less than in 1948. A drop of 14 percent in Mexican output more than offset smaller gains in Canada and elsewhere. Current gold and silver world-production rates are far below prewar averages.

Shaft sinking and continued exploratory drilling in the vicinity of Odendaalsrus, Orange Free State, 150 miles southwest of Johannesburg, brought this promising field nearer to production. In Canada, where output of gold had been stimulated by the subsidy program inaugurated in December 1947, bonuses at the end of 1949 were to be reduced $3.50 an ounce, the amount added to the value of gold as a result of the devaluation of the Canadian dollar in September 1949.

The pressure to reprice gold upward increased during 1949. As the exigencies of war had forced governments to limit the flow of gold and the conversion of foreign credits, black markets in gold developed in many parts of the world. The International Monetary Fund, in cognizance of such developments, expressed its disapproval in a statement issued by its Executive Board on June 18, 1947, as follows:

Exchange stability may be undermined by continued and increasing external purchases and sales of gold at prices which directly or indirectly produce exchange transactions at depreciated rates. From information at its disposal, the Fund believes that unless discouraged this practice is likely to become extensive, which would fundamentally disturb the exchange relationships among the members of the Fund. Moreover, these transactions involve a loss to monetary reserves, since much of the gold goes into private hoards rather than into central holdings. For these reasons, the Fund strongly deprecates international transactions in gold at premium prices and recommends that all of its members take effective action to prevent such transactions in gold with other countries or with nationals of other countries.

The Union of South Africa, however, took the position that gold producers were being required to make "disproportionate sacrifices" in the Fund's program for monetary and exchange stabilization. In September 1949, at the Fourth Annual Meeting of the Governors of the International Monetary Fund, the Governor for the Union of South Africa proposed the following resolution:

WHEREAS, it is the desire of all members of the International Monetary Fund to persevere in their endeavour to secure international co-operation in monetary and foreign exchange matters on the basis accepted by the Bretton Woods Conference, and

WHEREAS, it would be unreasonable to attempt to secure such co-operation on the basis of disproportionate sacrifice by members producing gold, and

WHEREAS, the price for gold used for monetary purposes in terms of Article IV, Section I, of the Articles of Agreement of the International Monetary Fund has remained unchanged since the inception of the Fund, and

WHEREAS, the prices of other commodities have in the meantime increased by substantial margins, and

WHEREAS, the maintenance of stable exchange rates is the reason for fixing the price of gold at the same figure over considerable periods of time, and

WHEREAS, the maintenance of the price at present fixed in terms of the Fund Agreement has, in the face of the substantial increase in the price-level of other commodities, only been secured at heavy, disproportionate and unjustifiable cost to countries producing gold, and

WHEREAS, it is permissible in terms of the Fund Agreement to sell newly-mined gold in any market.

SO THEREFORE, it is now Resolved by the Governors of the International Monetary Fund that nothing in the Articles of Agreement of the Fund shall be interpreted to prevent the sale, by the Government of any member, of newly-mined gold in any market at such premium prices as may be ruling in that market provided the said member sells to the Fund or to one or more members of the Fund, or transfers to its own monetary reserves at least fifty per cent of its newly-mined gold at the price from time to time current in terms of the Articles of Agreement of the Fund.

After study of the South African proposal and review of the Fund's 1947 statement of position, the Executive Board recommended on April 24, 1950 that the Board of Governors do not adopt the resolution of the Governor for the Union of South Africa.

The position expressed in the South African resolution had found wide support among domestic gold miners. Other United States interests, however, supported the Fund's position, in the belief that an increased quantity of gold available for hoarding would absorb funds, particularly in Economic Cooperation Administration countries, that otherwise would be available for foreign exchange support and for import of materials needed in economic rehabilitation. As a result, it was argued that the demands on the United States Government for grants and other support would be increased and in effect the United States would finance, in part at least, accumulation of gold in foreign privately held hoards.

The premiums paid by foreign hoarders for gold are difficult to determine. Much of the trade has been conducted in black markets and involved the violation of laws with attendant secrecy. In most markets the currency exchanged for gold was not freely exchangeable for United States dollars, and consequently quotations calculated in dollars were not necessarily realizable. During 1949 the premiums trended downward. For example, in the Paris free market bar gold was reported at $50 an ounce in May 1949, but a year later a similar quotation placed the price at $41.

A clarification of Treasury regulations promulgated under the Gold Reserve Act of 1934 governing the sale of gold with regard to transactions in unprocessed or "natural" gold came late in 1948. The legality of domestic trade and holding of "natural" gold, under section 19 of the Provisional Regulations issued under the act, was established in these terms:

> Gold in its natural state may be acquired, transported within the United States * * * without the necessity of holding a license therefor.

As a result, much publicity was given in 1948 and 1949 to the possibilities of producers developing a premium market for their product among hoarders preferring gold to currency and speculators anticipating a rising price for the metal. Production that could qualify as "natural" gold suitable for trading was limited. Most placer gold was disqualified because of amalgamation during recovery—neither

amalgam nor sponge gold was termed "natural." Some placer gold is recovered without mercury, and some operators could recover a "natural" gold product with a very small change in the washing methods. In addition to "natural" gold recovered from gravels, a few lode-mine operators found it practicable to recover from their ores free gold that would qualify as "natural" gold.

A special canvass was made of 1948 gold producers to determine the quantity of "natural" gold sold at premium prices and the total amount of the premiums. A similar canvass was made for 1949 data. Most of the gold producers reported no such sales in either year. Not all those reporting were willing to furnish data on quantities sold and premiums received. However, it is estimated that domestic "natural" gold containing 29,000 fine ounces of gold reached the premium market in 1949 compared with an estimated 25,000 fine ounces in 1948. In 1949 approximately three-quarters of the metal was mined in Alaska, but substantial sales of California and Montana material were made. Although rumors of high premiums continued to circulate, an extensive field check indicated the premium price to have averaged between $39 and $40 in 1949 compared to reports of substantial sales up to $43 or a little higher in 1948. The premium market appeared to have grown less attractive to producers toward the end of 1949. One large producer reporting over 3,000 fine ounces on hand at the end of the year stated that provision for collecting gold in its "natural" state was being discontinued. Mint receipts in early 1950 included a disproportionate quantity reported as having been recovered in 1949, indicating that some producers were accepting the Treasury price for gold they had been holding for the premium market. Probably some gold remained in the hands of producers when the canvass on which this chapter's domestic production statistics are based was closed. Such gold as is reported will be credited to the output of subsequent years. The quantities that may be involved will be very small compared with current production.

To facilitate the "natural" gold trade, methods have been devised for packaging and providing acceptable assays of lot fineness. The use of sealed-leather pokes and the casting of predetermined quantities of gold dust of known fineness in transparent plastic blocks were reported among the methods of preparing suitable hoarding and trading units. At least one large New York brokerage firm dealing in securities and commodities provided a standard contract for the sale and delivery of gold.

The United States Treasury buying price for gold throughout 1949 continued at $35 per fine ounce.

International trade in silver was dominated by the regulations of various governments. The United States Treasury continued to purchase silver mined domestically after July 1, 1946, at $0.9050505+ per fine ounce, a price substantially above the New York price for metal that could not qualify for Treasury acceptance. Import duties imposed in India resulted in the Bombay silver market operating almost completely on an internal basis. The New York market experienced an even greater degree of stability during 1949 than in 1948, with a range from a low of $0.7025 to a high of $0.7350 per ounce of silver 0.999 fine in 1949 compared with $0.7025 and $0.7775, respectively, in 1948.

Salient statistics of gold and silver in the United States,[1] 1940–44 (average) and 1945–49

	1940–44 (average)	1945	1946	1947	1948	1949

[1] Philippine Islands and Puerto Rico excluded.
[2] Less than 0.5 percent.
[3] Owned by Treasury Department; privately held coinage not included.

Silver consumed for coinage, particularly for China, Saudi Arabia, Mexico, Sweden, and the United States, totaled close to 70,000,000 ounces in 1949 and greatly exceeded the quantities returning to the world markets for demonitization programs. This was a marked net gain in coinage absorption over 1948, and was made despite the cutting in half of the quantity used in the United States for this purpose.

The net inflow of gold, reestablished in 1946 after a period when war expenditures had depleted United States holdings, increased in volume in 1947 and continued nearly unabated in 1948; it dropped to 41 percent of the 1948 total in 1949. Recent gains resulted in the establishment of new all-time monthly highs in United States stocks from January 1948 until the end of August 1949, following which stocks dropped slightly but, nonetheless, remained close to peak levels through the remainder of the year. Likewise, the net inflow of silver was resumed in 1946, increased in 1947 and 1948, but dropped 14 percent in 1949.

DOMESTIC PRODUCTION

Production of gold and silver in the United States is measured at mines and refineries. Both measures are tabulated by States of origin, but there is a small annual variation between them explained largely by time lag. Over a period of years, the deviations are found to be negligible. Compared with the mine reports compiled by the Bureau of Mines, the refinery reports compiled by the Bureau of the Mint in cooperation with the Bureau of Mines for the 45 years, 1905–49, show a total excess of gold of 184,363 ounces (a difference of 0.12 percent) and a total excess of silver of 15,832,478 ounces (a difference of 0.65 percent).

Gold and silver produced in the United States, 1905–49, in fine ounces, according to mine and mint returns, in terms of recoverable metals

Year	Mine		Mint	
	Gold	Silver	Gold	Silver
1905–44	142,725,645	2,286,938,209	143,063,806	2,300,377,419
1945	968,062	29,024,197	928,893	29,063,255
1946	1,574,505	22,914,604	1,462,354	21,103,269
1947	2,109,185	35,823,563	2,165,318	38,587,069
1948	2,014,257	38,096,031	2,025,480	39,228,468
1949	1,991,783	34,674,952	1,921,949	34,944,554
Total 1905–49	151,383,437	2,447,471,556	151,567,800	2,463,304,034

MINE PRODUCTION

During the war years 1943–45, for the first time on record, over half of the domestic gold output was recovered from base-metal ores, but in the years since both dry ores and placer gravels exceeded base-metal ores in yield of gold. This recovery in gold mining, however, has not restored the industry to its prewar level. High wages, difficulties in recruiting labor forces, and high prices for equipment and supplies, together with an unchanged gold price, retarded recovery. In 1949 the slight downtrend begun in 1948 was continued, and production amounted to 41 percent of the all-time peak established in 1940.

Silver production, which had declined without interruption from 1940 to 1946, reversed the trend in 1947 and by 1948 was 66 percent

above the 1946 low. Output in 1949, however, fell 9 percent compared with 1948. An analysis of silver production, by ores, shows that approximately three-fourths was recovered as a byproduct from base-metal ores from 1945 to 1949. Moreover, all of the silver recovered at placers and part of that produced from dry ores were byproducts of operations carried on chiefly for gold.

All tonnage figures used in this report are short tons of 2,000 pounds "dry weight"; that is, they do not include moisture. Figures in cubic yards used in measuring material treated in placer operations are "bank measure"; that is, the material is measured in the ground before excavation. The weight unit for gold and silver is the troy ounce (480 grains). The totals are calculated upon the basis of recovered and recoverable fine gold and silver shown by assays to be contained in ore, bullion, and other material produced.

Mine production of gold and silver in the United States, in 1949, by months, in fine ounces

	Gold	Silver		Gold	Silver
January	104,711	2,595,454	August	190,281	2,963,793

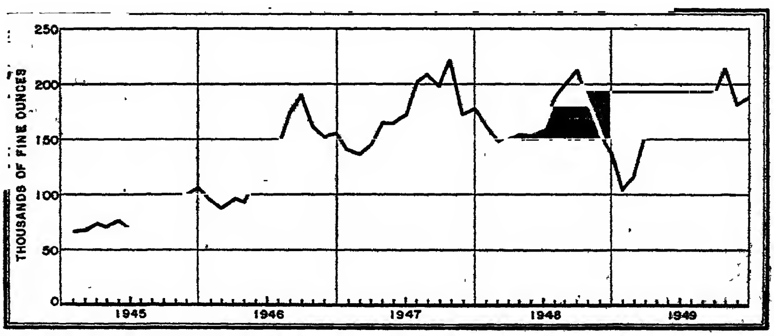

FIGURE 1.—Mine production of gold in the United States, 1945–49, by months, in terms of recoverable gold.

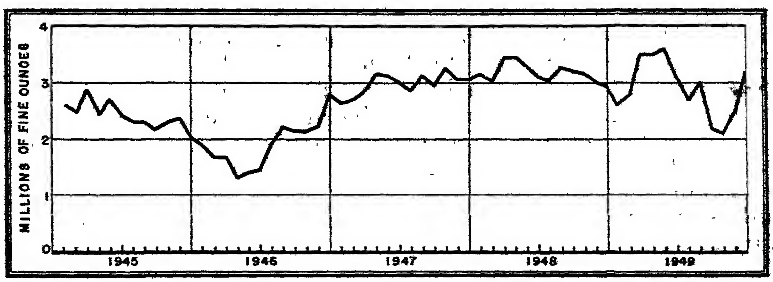

FIGURE 2.—Mine production of silver in the United States, 1945–49, by months, in terms of recoverable silver.

Mines are grouped into two main classes—placers and lodes. The placers are those in which gold and silver as native metals or in natural alloy and, in a few placers, platinum are recovered from gravel. Except for such small-scale hand methods as those utilizing the gold pan, the rocker, or the dry washer, all placer recovery methods employ sluice boxes; methods are distinguished by the means used for delivering the gravel to the sluices. Those methods where gravel is delivered mechanically include bucket-line dredging, drag-line dredging, and treatment in nonfloating washing plants of gravel delivered by power shovel, drag-line excavator, truck, slack-line scraper, or other mechanical means. In the hydraulic method the gravel is mined from the bank by a powerful jet of water; in some small-scale hand methods the gravel is shoveled into sluices; and in drift operations the gravel is mined underground and delivered to sluices at the surface. The lode mines are those yielding gold and silver from ore (as distinguished from gravel), mainly from underground workings and, in addition to those worked chiefly for one or both of the precious metals, include those that yield ore mined chiefly for copper, lead, zinc, or other metals but contribute the precious metals as byproducts. As far as possible, the mine unit used is not the operator but the mining claim or group of claims.

Principal Mining Districts and Leading Mines

One of the anomalies of the war economy was the emergence of a copper district—West Mountain (Bingham), Utah—as the leading gold producer in the United States, surpassing Lawrence County (Lead), S. Dak., in 1943, 1944, and 1945. In 1946, however, Lawrence County regained the lead, a position held through 1949; the West Mountain district has ranked second in this period. Half of the domestic mine output was mined in the four leading districts in 1949. Among the first four districts is the Yukon River Basin, Alaska, with 151,262 ounces in 1949 and 189,143 ounces in 1948.

The leading silver districts for many years have included many noted more for base-metal output than for silver yield, and this condition was unchanged in 1949. The three leading districts produced more than half of the total United States output of silver in 1949.

Of the 25 leading gold-producing mines, 8 were lode gold mines, 6 were placers worked by bucket-line dredges, 3 were copper mines, 1 was a lead-zinc mine, and 1 was a copper-zinc mine; 6 produced more than 1 type of ore. The 3 leading mines contributed 41 percent of the total gold produced in the United States in 1949 and the 25 on the list, 73 percent.

Only 3 of the 25 leading silver-producing mines depended exclusively on silver ore; ores valuable chiefly for copper, lead, zinc, and gold supplied most of the silver production. The seven leading mines each producing over 1,000,000 ounces of silver in 1949 contributed 46 percent of the United States total. The list of 25 mines supplied over two-thirds of the United States output. As several operators worked more than one of the leading silver mines as well as smaller producers, the output of silver by companies was substantially more concentrated than by mines.

Mine production of recoverable gold in the United States, 1940–44 (average), by districts that produced 10,000 fine ounces or more during any year, 1945–49, in fine ounces [1]

[1] Bureau of Mines not at liberty to publish figure.

Twenty-five leading gold-producing mines in the United States in 1949, in order of output

Rank	Mine	District	State	Operator	Source of gold
1	Homestake	Whitewood	South Dakota	Homestake Mining Co.	Gold ore.
2	Utah Copper	West Mountain (Bingham)	Utah	Kennecott Copper Corp.	Copper ore.
3	Fairbanks Unit	Fairbanks	Alaska	U. S. Smelting, Refining & Mining Co.	Dredge.
4	Natomas	Folsom	California	Natomas Co.	Do.
5	New Brunswick-Idaho-Maryland	Grass Valley-Nevada City	do	Idaho Maryland Mines Corp.	Gold ore.
6	Yuba Unit	Yuba River	do	Yuba Consolidated Gold Fields	Dredge.
7	Yellow Pine	Yellow Pine	Idaho	Bradley Mining Co.	Gold, gold-antimony ores.

8	Empire Star group	Grass Valley-Nevada City	California	Empire Star Mines, Ltd	Gold ore.
9	Holden	Chelan Lake	Washington	Howe Sound Co	Zinc-copper ore.
10	New Cornelia	Ajo	Arizona	Phelps Dodge Corp	Copper ore.
11	Ruth & Copper Flat	Robinson (Ely)	Nevada	Kennecott Copper Corp	Do.
12	Nome	Nome	Alaska	U. S. Smelting, Refining & Mining Co.	Dredge.
13	Smuggler-Union, etc	Upper San Miguel	Colorado	Telluride Mines, Inc	Gold ore.
14	Knob Hill	Republic (Eureka)	Washington	Knob Hill Mines, Inc	Do.
15	Getchell & Pinson-Ogee	Potosi	Nevada	Getchell Mines, Inc	Do.
16	Capital Dredges	Folsom	California	Capital Dredging Co	Dredge.
17	Old Eureka	Mother Lode	do	Central Eureka Mining Co	Gold ore.
18	United States & Lark	West Mountain (Bingham)	Utah	U. S. Smelting, Refining & Mining Co.	Zinc-lead, gold-silver, silver ores.
19	Goldacres	Bullion	Nevada	London Extension Mining Co	Gold ore.
20	Butte Unit	Oroville	California	Yuba Consolidated Gold Fields	Dredge.
21	Park Galena-Mayflower	Park City	Utah	New Park Mining Co	Zinc-lead ore.
22	Butte Mines	Summit Valley (Butte)	Montana	Anaconda Copper Mining Co	Copper, zinc-lead ores.
23	Iron King & Ext	Big Bug	Arizona	Shattuck Denn Mining Co	Zinc-lead, gold-silver, gold ores.
24	Treasury Tunnel-Black Bear	Upper San Miguel	Colorado	Idarado Mining Co	Zinc-lead-copper ore.
25	Magma	Pioneer (Superior)	Arizona	Magma Copper Co	Copper, silver ores.

Twenty-five leading silver-producing mines in the United States in 1949, in order of output

Rank	Mine	District	State	Operator	Source of silver
1	Butte Mines	Summit Valley (Butte)	Montana	Anaconda Copper Mining Co	Copper, zinc-lead ores.
2	Sunshine	Evolution	Idaho	Sunshine Mining Co	Silver ore.
3	Utah Copper	West Mountain (Bingham)	Utah	Kennecott Copper Corp	Copper ore.
4	United States & Lark	do	do	U. S. Smelting, Refining & Mining Co	Zinc-lead, gold-silver, silver ores.
5	Bunker Hill & Sullivan	Yreka	Idaho	Bunker Hill & Sullivan Mining & Concentrating Co.	Zinc-lead ore.
6	Copper Queen	Warren (Bisbee)	Arizona	Phelps Dodge Corp	Copper, zinc-lead ores.
7	Polaris	Evolution	Idaho	Sunshine Mining Co	Silver ore.
8	Chief, etc	Tintic	Utah	Chief Consolidated Mining Co	Zinc-lead, lead, silver ores.
9	Morenci	Copper Mountain	Arizona	Phelps Dodge Corp	Copper ore.
10	Page	Yreka	Idaho	Federal Mining & Smelting Co	Zinc-lead ore.
11	Iron King & Ext	Big Bug	Arizona	Shattuck Denn Mining Corp	Zinc-lead, gold, gold-silver ores.
12	St. Germain-Purim	Evolution	Idaho	Silver Dollar Mining Co	Lead ore.
13	Pioche group	Pioche	Nevada	Combined Metals Reduction Co	Zinc-lead ore.
14	United Verde	Verde (Jerome)	Arizona	Phelps Dodge Corp	Copper, zinc-copper ores.
15	New Cornelia	Ajo	do	do	Copper ore.
16	Triumph	Warm Springs	Idaho	Triumph Mining Co	Zinc-lead ore.
17	Treasury Tunnel-Black Bear	Upper San Miguel	Colorado	Idarado Mining Co	Zinc-lead-copper ore.
18	Shenandoah, etc	Animas	do	Shenandoah-Dives Mining Co	Gold-silver ore.
19	Magma	Pioneer (Superior)	Arizona	Magma Copper Co	Copper, silver ores.
20	Darwin group	Coso (Darwin)	California	Anaconda Copper Mining Co	Zinc-lead ore.
21	Park Galena-Mayflower	Park City	Utah	New Park Mining Co	Do.
22	Sherman	Lelande	Idaho	Day Mines, Inc	Lead ore.
23	Butterfield	West Mountain (Bingham)	Utah	Combined Metals Reduction Co	Zinc-lead ore.
24	Amethyst, etc	Creede	Colorado	Emperius Mining Co	Silver ore.
25	Emma	Summit Valley (Butte)	Montana	Anaconda Copper Mining Co	Zinc-lead ore.

Mine production of recoverable gold in the United States, 1939–49, with production of maximum year, and cumulative production from earliest record to end of 1949, by States, in fine ounces

[1] States east of the Mississippi figures are peaks since 1896, except New York and Pennsylvania which are peaks since 1905. The Illinois figure is the peak since 1907. Alaska, California, Nevada, and Oregon are peaks since 1880.
[2] Includes a small quantity by New Hampshire.

Ore Production, Classification, Metal Yield, and Methods of Recovery

The following tables give details of classes of ore, metal yield in fine ounces of gold and silver to the ton, and gold and silver output by classes of ore and by methods of recovery, embracing all ores that yielded gold and silver in the United States in 1949. These tables were compiled from the individual State chapters in this volume, in which more detailed data are presented.

The classification originally adopted in 1905 on the basis of smelter terminology, smelter settlement contracts, and metal recovery has been used continuously in succeeding years, except for modifications necessitated by the improvement in metallurgy and the lowering of the grade of complex ores treated. The copper ores include those smelting ores that contain 2.5 percent dry assay or more of copper (or less than this percentage if no other metal is present); or those ores concentrated chiefly for their copper content. The lead ores are those that contain 5 percent dry assay (minimum lead smelting charge requires 7.5 to 8.5 percent wet assay) or more of lead, irrespective of precious-metal content; and ore that carries any grade of lead exclusively is called a lead ore. Zinc smelting ores (chiefly oxides) had ranged from 16 to 45 percent zinc, but with the development of slag fuming, which permits some oxidized ore in the charge, and with high zinc prices, the minimum has declined to as low as 5 percent recoverable zinc; zinc concentrating ores include any grade of zinc ore that makes marketable zinc concentrate, irrespective of precious-metal content. The mixed ores are combinations of those enumerated.

Ore produced in the United States and average recovery, in fine ounces, of gold and silver per ton in 1949 [1]

[1] Missouri excluded.
[2] Includes 22,389 tons of old lead-smelter slag.
[3] Includes 14,585 tons of old zinc slag fumed.
[4] Includes metal recovered from tungsten ore.
[5] 16 tons lead concentrates derived from zinc-lead ore milled and recorded in 1948, but shipped in 1949.
[6] Includes 17,480 tons of zinc slag.
[7] Excludes magnetite-pyrite-chalcopyrite ore and gold and silver therefrom.

Gold, gold-silver, and silver ores containing too little copper, lead, or zinc to be classified as copper, lead, zinc, or mixed base-metal ores are called "dry" ores, regardless of the ratio of concentration, except low-grade ore milled chiefly for its copper content and having very little or no precious-metal content (chiefly the "porphyry coppers") and ores from which separate products of lead concentrates and zinc concentrates are made. The crude ore into the mill in these two exceptional instances thus takes its name from its products—a name that is also justified by the mineralogical content and final recovery of metals. The "dry ores" thus are ores, chiefly siliceous, valuable for their gold and silver content and, in some instances, for their fluxing properties, regardless of method of treatment. Dry gold ores are those that by inspection are overwhelmingly of gold content; a similar qualification applies to silver ores; decision as to "gold-silver" ore is made on a basis of value, using the rule that the bimetal classification is not used unless the metal of lower value equals or exceeds one-quarter of the combined value of the gold and silver.

The lead, zinc, and zinc-lead ores in most districts in the States east of the Rocky Mountains carry no appreciable quantity of gold or silver; such ores are excluded from this report unless otherwise indicated.

Mine production of gold in the United States, 1940–44 (average) and 1945–49, by percent from sources and in total fine ounces

[1] Less than 0.01 percent.
[2] Gold and silver produced by cyanidation included with amalgamation.

Placers

More than one-fourth of the gold produced in 1949 was derived from placer mines. Of the 532,735 ounces of placer gold, 424,577 ounces or 80 percent was recovered by bucket-line dredges. Although this dredge output was over fourfold that of 1944, the wartime low, it was far below the all-time high of 904,149 ounces established in 1940. A number of dredge properties remained idle during 1949 because of the unfavorable economic situation for gold production.

As gold dredges are not converted readily to other uses, many idle properties had much of their operating equipment intact. It appeared probable, therefore, that gold output from this type of mining would be expanded if the ratio of gold price to dredging cost improved appreciably.

The quantity of gold recovered by bucket-line dredges from the inception of the industry as a commercial factor in 1896 to the end of 1949 is recorded as 21,326,062 ounces, originating by States as follows: California, 12,787,011 ounces; Alaska, 5,900,803 (including the production from single-dipper dredges and some gold by hydraulicking); Montana, 782,473; Idaho, 670,627; and other States, 1,185,148.

The second most important source of placer gold was the nonfloating-washing-plant method, with mechanical earth-moving equipment for gravel delivery. This was the only one of the more productive methods to show increased output in 1949 compared with 1948, a repetition of the condition that existed in 1948. Production by this method has shown an uninterrupted rise since 1944. Dragline dredging, a method that had risen phenomenally from 1933 until World War II, remained in third place in 1949. Of the other methods, hydraulicking was the most productive, although sharp decreases in 1949 and 1948 reduced output to less than twice that recorded for small-scale hand methods.

California produced 47 percent of the United States placer gold in 1949 and Alaska, 42 percent. Other large producers, named in order of importance, were Idaho, Oregon, Colorado, Montana, and Nevada. In 1949 California was the leader in all but three methods of placer-gold production. Alaska led in hydraulic and nonfloating-washing-plant production and Nevada in dry placering.

The accompanying table shows the placer gold produced in the United States, classified by mining methods, in 1945–49.

Additional information on placer mining may be found in the State reviews in this volume.

Gold production at placer mines in the United States, by classes of mines and methods of recovery, 1945–49

[1] A mine using more than one method of recovery is counted but once in arriving at total for all methods.

REFINERY PRODUCTION

The accompanying table contains official estimates of production of gold and silver in the United States, made by the Bureau of the Mint, based upon arrivals at United States mints and assay offices and at privately owned refineries. The mints and assay offices determine the State source of all newly mined unrefined material at the time deposits are received. The State source of material received by privately owned refineries is determined from information submitted

by them and by intervening smelters, mills, etc., involved in the reduction processes.

Gold and silver refined in the United States, 1945–49, and approximate distribution of source, by States, in 1949, in fine ounces

[1] From Report of the Director of the Mint. The estimates for 1792–1873 are by R. W. Raymond, Commissioner of Mining Statistics, Treasury Department, and since then, by the Director of the Mint.
[2] Gold valued in 1934 and thereafter at $35 per fine ounce; prior thereto, at $20.67+ per fine ounce.
[3] Silver valued in 1934 and thereafter at Government's average buying price for domestic product.

CONSUMPTION AND USES IN INDUSTRY AND THE ARTS

Monetary use has claimed by far the largest part of the gold and silver output through the years, but this use to a large extent takes the form of stockpiling in Government and private hoards that can be made available to industry and the arts without smelter or refinery preparation. In contrast, the gold and silver that enter industry and the arts are consumed much as are other metals, any return as second-

ary metal requiring the usual channels of collection, smelting, and refining. The consumption of gold and silver in the arts antedates written history, but industrial use of these two metals is a comparatively recent development.

Gold.—The arts require a much larger quantity of gold than does industry, but its corrosion-resistant and other properties have resulted in some industrial demand. Consumption in the arts increased rapidly during the war. A high marriage rate and widespread prosperity have increased the sale of jewelry, watches, and many luxury items made from gold. Comparison of 1949 gold figures with those for 1948 shows an 11-percent decrease in the return from industrial use contrasted with increases of 65 percent in issue for industrial use and 142 percent in net consumption. The issue for industrial use in 1949 was far below the level prevailing in 1946 but considerably above other recent years, whereas net use, although also far below 1946, virtually coincided with that in 1945. The net absorption by industry and the arts equaled over one and one-half times the total new gold produced from domestic mines during 1949 compared with less than two-thirds in 1948.

Net industrial consumption of gold and silver in the United States, 1940–44 (average) and 1945–49

[U. S. Bureau of the Mint]

Year	Gold (dollars)			Silver (fine ounces)		
	Returned from industrial use	Issued for industrial use	Net industrial consumption	Returned from industrial use	Issued for industrial use	Net industrial consumption
1940–44 (average)	24,699,094	80,947,913	56,248,819	34,649,557	125,935,540	91,285,983
1945	30,991,905	139,936,237	108,944,332	58,360,767	184,660,767	126,300,000
1946	45,999,837	199,686,837	153,687,000	36,646,860	123,646,860	87,000,000
1947	49,229,578	98,129,578	48,900,000	27,866,359	126,366,359	98,500,000
1948	45,142,764	90,128,764	44,986,000	23,897,173	129,186,173	105,289,000
1949	40,133,100	148,975,571	108,842,471	22,660,459	110,660,459	88,000,000

Silver.—The 1949 consumption of silver in industry and the arts was the smallest since 1941 except for 1946; the 1949 total slightly exceeded that for 1946. Consumption nonetheless was high in relation to prewar totals and exceeded any annual output ever achieved by domestic mines.

Widespread prosperity and a high marriage rate sustained postwar demand for sterling and plated silverware, jewelry, watch cases, church articles, pens, pencils, and other items largely in the luxury class. Consumption was large in photography, particularly for motion pictures. The industrial uses of silver had grown greatly during the war and continued to absorb much silver thereafter, although on a reduced scale in 1949.

MONETARY STOCKS

Gold holdings of the United States rose $183,000,000 (1 percent) from $24,244,000,000 on January 1, 1949, to $24,427,000,000 on January 1, 1950, according to the Federal Reserve Bulletin. Total world reserves are not positively known, inasmuch as data are not available from some countries, including Germany, Japan, Australia,

and U. S. S. R. Currency stabilization funds secretly held add to the difficulties in reaching an approximation.

Foreign gold reserves increased rapidly after the United States entered the war late in 1941, largely because United States war purchases abroad so greatly exceeded commercial exports in value. During the war period foreign reserves increased nearly $5,000,000,000, and United States reserves decreased over $2,500,000,000. Sharing prominently in the increase were Switzerland, Sweden, Turkey, Iran, Spain, Union of South Africa, and Latin American countries. In 1946, however, there was a reversal in the direction of the flow of gold, and the United States net increase in 1948 substantially exceeded world mine output; the excess in 1949 amounted to less than 20 percent of the world total.

United States Treasury silver holdings increased 26,000,000 fine ounces during 1949 to 1,978,000,000 ounces. The holdings do not include 410,553,011 ounces released under lend-lease agreements that provide for return of the silver.

PRICES

Since January 1934 the price of gold at the United States Mint has been $35 per fine troy ounce. The Treasury buying price for silver domestically mined after July 1, 1939, was fixed at $0.711+ per ounce on July 6, 1939; on July 31, 1946, the President approved an act (Public Law 579, 79th Congress) which provided that the seigniorage to be deducted for silver mined after July 1, 1946, and delivered to the Treasury be reduced from 45 percent to 30 percent. The effect was to raise the price of domestically mined silver to 90.50505+ cents an ounce; there has been no price change since.

According to the Director of the Mint, the following prices for silver prevailed in London and New York (exchange-free—New York on London, January 1948–August 1949, $4.03; September 1949, $3.44; October–December 1949, $2.80) in 1948 and 1949: London price, per ounce, 0.999 fine, opened in 1948 at 45d., a level maintained past midyear when after a short upward movement the price fell to 42.5d. by the year end. Changes in 1949 were of little significance until devaluation of the pound in September following which the price rose to 64d. where it remained the rest of the year. New York price, per ounce, 0.999 fine, opened in 1948 at $0.74625, a level held until August. After a small rise in the next 3 months the price declined to an average of $0.70000 in December. In early 1949 the price rose to $0.71500, where it held until September, then it rose to $0.73250 and continued at that level for the remainder of the year.

FOREIGN TRADE [1]

The excess of gold imports over exports dropped from nearly 1¾ billion dollars in 1948 to 41 percent of that amount in 1949. The gains from imports plus the output from domestic mines greatly exceeded consumption in the arts and industries, and thus gold monetary stocks increased. Consumption of silver, however, exceeded the supply from mine output plus net imports, with the result that stocks were drawn upon.

[1] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Value of gold and silver imported into and exported from the United States, 1945–49

[U. S. Department of Commerce]

	Imports	Exports	Excess of imports over exports [1]
Gold:			
1945	$93,718,050	$199,967,940	−$106,249,890

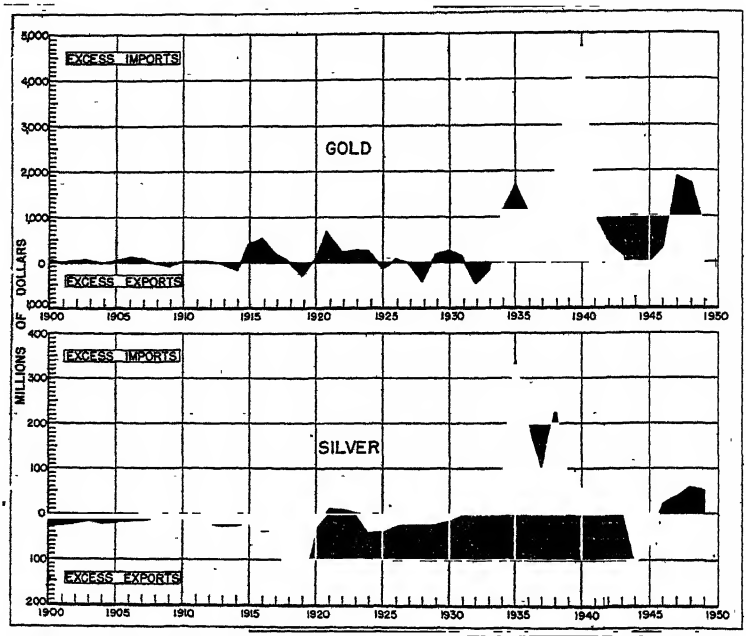

FIGURE 3.—Gold and silver imports and exports, with net movements, 1900–1949.

WORLD REVIEW

World gold output rose slightly in 1949, continuing the movement in progress since 1946, but the 1949 total continued considerably below annual quantities produced before World War II. Devaluation of the British pound and many other currencies in September 1949

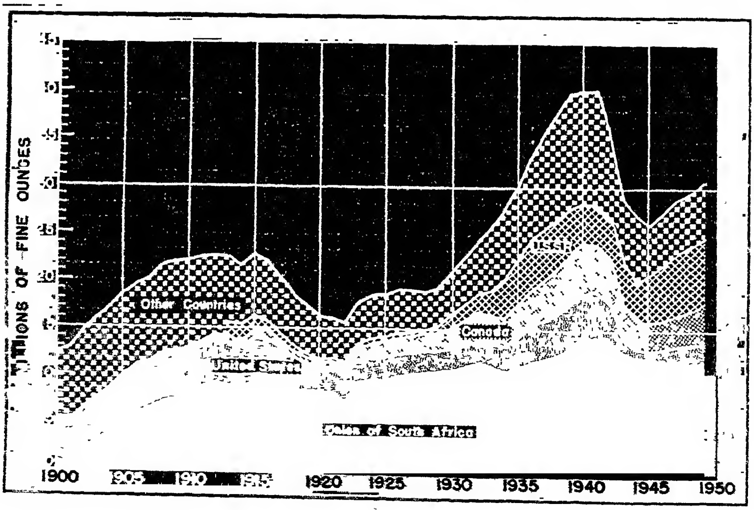

FIGURE 4.—World production of gold 1900–1949.

should result in increased production outside the United States. World silver output dropped slightly in 1949, owing largely to declines in Mexico and the United States that were not offset by gains in other silver-producing areas.

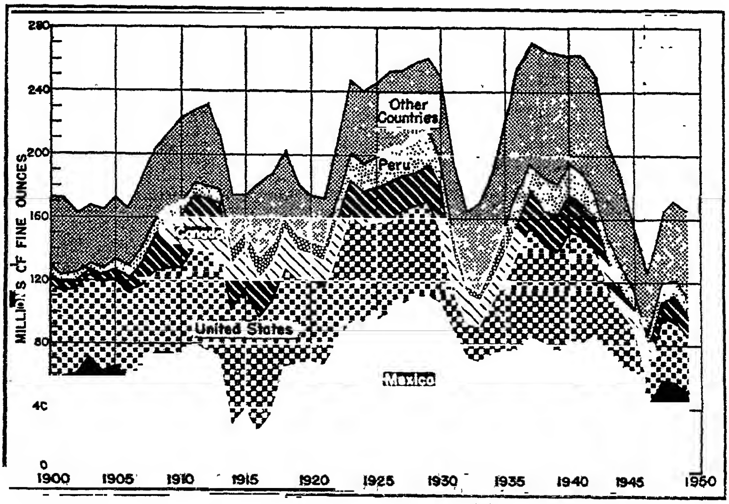

FIGURE 5.—World production of silver, 1900–1949.

See footnotes on next page.

[1] Figures used derived in part from American Bureau of Metal Statistics. For some countries accurate figures are not possible to obtain owing to clandestine trade in gold. Data not available for Austria, Bulgaria, Germany, Norway, and Yugoslavia; estimate not included in total. In addition, production in Indonesia and Papua was negligible, and Thailand produced none in 1944–47.
[2] Refinery production. Excludes production of the Philippines.
[3] Data revised as recent information states the gold in zinc concentrates is not recoverable.
[4] Imports into United States.
[5] Exports.
[6] Estimate.
[7] Data not available; estimate included in total.
[8] Includes gold mined in Transylvania which temporarily formed part of Hungary.
[9] Output from U. S. S. R. in Asia included with U. S. S. R. in Europe.
[10] Lode only.
[11] Figure published by Director of the Mint, representing gold of Philippine origin refined but not necessarily mined during the year.
[12] Includes Ruanda-Urundi.
[13] Included is yield from Nkana mine refinery slimes accumulated during the war: 6,594 ounces in 1946, 547 in 1947, 999 in 1948, and 972 in 1949.

World production of silver, 1944–49, by countries, in fine ounces [1]

[1] Silver is also produced in Bulgaria, Greece, Hong Kong, Federation of Malaya, Indonesia, Poland, Sarawak, Sierra Leone, Turkey, U. S. S. R., and Yugoslavia; production data are not available, but estimates are included in total.
[2] Excludes the Philippines.
[3] Imports into the United States. Scrap is included in this figure in many instances, most notably in the case of Cuba.
[4] Exports.
[5] Estimate.
[6] Data not available; estimate included in total.
[7] American and British zones only.
[8] Data represent Trianon Hungary after October 1944.
[9] Recovered from an accumulation of refinery slimes.
[10] Fiscal year ended May 31 of year following that stated.

Australia.—Production of gold in Australia was virtually unchanged in 1949 as compared with 1948 and was 4 percent less than in 1947. Average monthly output in the first nine months of the year exceeded that in the final quarter, indicating that Australia failed to follow the general production pattern of the world which showed gold output on the rise after devaluation of the pound sterling in September 1949, and the increase in the price of gold in Australia from £10 15s. 3d. to £15 9s. 3d. Reports from Australia nonetheless indicated that devaluation had improved the outlook for gold production.

Canada.—Gold represents the chief value in Canadian mineral production; output of this metal places Canada at least third among world gold producers—after the Union of South Africa and doubtless also the U. S. S. R. As in the case of the Union of South Africa, devaluation of the Canadian dollar in September (which added $3.50 an ounce to the price paid for gold) helped to offset growing mining costs and benefited producers of gold. Output of gold rose 16 percent in 1949, and all territories but British Columbia (and in addition, Nova Scotia, where very small quantities are involved) shared the gain. The rise in 1949 marked continuation of the movement in progress since 1945. The Government subsidy to gold mines, scheduled to run 3 years from December 1947, was not expected to

extend beyond the end of 1950. Varying bonuses were paid to mines according to needs. At the end of 1949 the bonuses were to be reduced $3.50 an ounce; as a result, mines getting $3.50 an ounce or less would thereafter receive no bonus.

Output of gold in 1948 and 1949 was as follows, in fine ounces:

Province or Territory:	*1948*	*1949*
British Columbia	306, 998	301, 400
Manitoba and Saskatchewan	194, 103	234, 187
Northwest Territories	101, 625	178, 069
Ontario	2, 095, 377	2, 330, 108
Quebec	770, 625	972, 510
Yukon	60, 614	78, 577
Others [1]	266	9, 005
Total	3, 529, 608	4, 103, 856

[1] Alberta and Nova Scotia, and from May 1949, also Newfoundland.

Output of silver rose 5 percent in 1949, a continuation of the increase over the recent low rate in 1947. Canada ranks third also in silver production in the world, following Mexico and the United States in output of this metal.

Canada exported 6,211,912 ounces of refined silver and 4,054,614 ounces of silver in ores and concentrates, compared with 5,434,364 and 3,294,691 ounces, respectively, in 1948.

Colombia.—In production of gold Colombia leads other countries in South America by a substantial margin. According to a report [2] recently published, the value of gold produced in Colombia since the Spanish conquest has totaled nearly a billion dollars. This includes an estimated $639,000,000 worth (Spanish and Colombian currencies, approximately equivalent to United States currency) which together with $33,000,000 worth of silver was produced from 1537 to 1886. Prior to the Spanish conquest, the aborigines produced and used gold for ornaments and utensils.

The gold output fluctuated from about 300,000 ounces per year in 1915–20 to a low of 136,576 in 1929 and a peak of 656,028 in 1941. The report contains descriptions of the various gold-producing districts and mines.

Silver is recovered only as a byproduct of gold mining. In 1931–45, 2,757,473 ounces of silver were produced compared with 6,836,643 ounces of gold in the same period.

Honduras.—Honduras leads all other Central American countries in the output of silver and is exceeded by only five countries in the Western Hemisphere. According to Mineral Trade Notes,[3] the New York & Honduras Rosario Mining Co., operated the San Juancito and El Mochito mines in 1949. The former produced 2,283,068 ounces of silver and 15,393 ounces of gold, and the latter, 1,138,137 and 709 ounces, respectively. Smaller producers also contributed some gold. Exports of silver were 3,389,513 ounces in the fiscal year 1948–49 compared with 2,632,572 ounces in 1947–48, and of gold were 20,820 and 18,984 ounces, respectively.

[3] Bureau of Mines, Mineral Trade Notes: Gold and Silver—Honduras, vol. 30, No. 4, April 1950, pp. 9–10.

Japan.—Gold and silver in Japan was the subject of a recent report.[4] The report states that Japan has been a producer of gold and silver for centuries. Early gold output was largely from placer operations, but this method has decreased in importance and recently accounted for only about 1 percent of the total. As nearly as could be determined, from the incomplete source of material, the outstanding gold-silver producing mines are the Konomai, Kushikino, Teine, Oya, Taio, Sado, and Mochikoshi. The Konomai and Teine mines are in Hokkaido, the Kushikino in Kyushu, and the Mochikoshi on the Izu Peninsula on Honshu. These are the three most important gold districts in Japan. Considerable gold and silver have been produced as a byproduct of base metal mining operations. Japan's future gold and silver production, it was said, under present conditions will be confined almost entirely to that recovered as a byproduct, because other metal prices have tended to keep pace with inflation.

Mexico.—Mexico stands first in the world in output of silver, by a wide margin over the United States, which ranks second. After October 21, 1948, silver exports, whether in coins or bars, were subject to the approval of the Banco de Mexico. According to Handy and Harman,[5] it was believed that the bank was ready to accept all offers of Mexican refined production. Weakness in the dollar-peso exchange rate jeopardized the coinage program, and it was reported that only 900,000 ounces of silver were consumed by Mexico for internal coinage in 1949. Further minting of silver coins for domestic circulation was discontinued. The same source stated that, nonetheless, coinage elsewhere supplied the Bank of Mexico with a market for the principal part of the 57,000,000 ounces of silver disposed of in 1949. Early in the year negotiations with the Saudi Arabia Government resulted in two contracts for a total of nearly 13,500,000 ounces, and subsequent contracts called for sales to China of 32,500,000 ounces. An additional 5,000,000 ounces were in the form of old 0.9027 fine pesos destined for far eastern centers, and miscellaneous sales totaling 6,000,000 ounces were made in New York.

It is reported that the Bank of Mexico inaugurated in 1949 the minting of silver disks of sterling fineness, containing 1 ounce of pure silver, stamped with weight and fineness but with no monetary or face value indicated, in the expectation that the Far East might provide a ready market for such a barter coin. The conventional coins, however, evidently were much preferred; and it is said that only 1,000,000 of the new disks were struck, of which 900,000 remained in possession of the Bank.

At the end of the year, the Mexican Congress authorized a new domestic silver coinage program, providing for the minting of 1-peso, 50-centavo and 25-centavo coins, to be composed of 300 parts of silver, 100 parts nickel, 100 parts zinc, and 500 parts copper.

Union of South Africa.—The South African gold-mining industry benefited in 1949 from devaluation of the South African pound[6] on

September 19, virtually coincident with the devaluation of the British pound sterling, and partly as a result thereof production in this area in 1949 gained slightly as compared with 1948 and was the largest since 1946. In the early part of the year, gold was paid for by the Union Treasury at 172s. 6d. an ounce and beginning September 19 at the rate of 248s. 3d. an ounce. The increased price made it possible to treat ores containing smaller quantities of gold and the average content of 3.791 dwt. per ton in December marked a new record low figure. Other benefits were increased wages for European and native workers, greater earnings, and larger dividends. The increased pay was said to have attracted larger numbers of native laborers to the field and thus to have made possible the larger output from lower grade ores.

During the year arrangements were made for some of the gold produced to be sold for industrial and artistic purposes at a premium for the benefit of producers. This device yielded additional revenue of £1,066,949 in 1949, which is not included in the accompanying table.

Salient statistics of gold mining in the Union of South Africa, 1946–49

[Transvaal Chamber of Mines]

	1946	1947	1948	1949

Gypsum

By Joseph C. Arundale and M. G. Downey

GENERAL SUMMARY

THE year 1949 again witnessed high production of gypsum. Shortages of most gypsum products had largely disappeared by the end of 1948, as residential building on a seasonally adjusted basis declined from the third quarter of 1948 into the second quarter of 1949. During this period, easing of demand and growth of capacity permitted rapid inventory accumulations, which brought stocks of most gypsum products into adequate relation with sales. The trend of economic activity in the first half moved downward for the first time in the past few years of reconversion from war to peace. In the second half of 1949, a substantial recovery from this mild recession occurred in the field of residential building, as easy credit and high demand for housing continued through the end of the year.

Production of crude and calcined gypsum, imports of crude gypsum, and sales by producers of most gypsum products lagged behind 1948, but they were still high, in most instances the second highest on record. Most of the lag in sales probably was attributable to inventory liquidation by dealers.

At the end of 1949, many factors pointed to increased building activity; and forecasts for 1950 were very optimistic, indicating still more favorable marketing conditions for the gypsum industry.

[1] Each mine, plant, or combination mine and plant is counted as 1 establishment.
[2] Excludes byproduct gypsum.
[3] Made from domestic, imported, and byproduct crude gypsum.

DOMESTIC PRODUCTION

Crude.—Output of crude gypsum from mines in the United States totaled 6,608,118 short tons in 1949. This was the second greatest tonnage in any one year of record and only 9 percent less than the previous record set in 1948. Of the 60 active domestic mines that produced gypsum in 1949, 36 were open-pit operations, 17 were underground, and 7 were combinations of these two types. Mining was discontinued at two small mines in California, one in Nevada, and one in South Dakota.

A brief description of the quarrying operations of National Gypsum Co. at Rotan, Tex., was published.[1]

Calcined.—Fifty-one plants produced 5,767,163 short tons of calcined gypsum in 216 pieces of calcining equipment in 1949. The production of calcined gypsum is a good barometer of the activity in the industry because it includes both imported and domestic gypsum, and the bulk of gypsum products require calcined gypsum in their manufacture. It is interesting to note that production of calcined gypsum in 1949 doubled the tonnage produced in 1939.

Mine and Calcining Plant Developments.—Producers continued to mechanize, modernize, standardize, and expand operations, and efforts were made to improve efficiency and reduce costs. National Gypsum Co., for example, set goals of a $1,500,000 reduction in operating costs in 1949 and $1,000,000 in 1950. To accomplish this, the company planned readjustment of ship-unloading facilities and techniques on the east coast, standardization of high-speed production methods, standardization of new manufacturing methods, and better employee training to increase productivity.[2]

National Gypsum Co. completed a $3,500,000 expansion program at its Clarence Center, N. Y., mine, involving complete modernization and mechanization.[3]

The Gypsum Products Co. of Cody, Wyo., was purchased by the Interstate Chemical Co. of Seattle, Wash. The transaction included the company mill, warehouse, and gypsum holdings west of Cody.[4]

The Union Plaster Co., Phoenix, Ariz., changed its name to Union Gypsum Co. and is maintaining shipments of gypsum at the rate of about 1,000 tons monthly from its open-pit operation in the Saddle Mountain district near Winkelman, Ariz.[5]

Westates Agricultural Chemical Co. announced acquisition of Northwest Gypsum Co., Colfax, Wash., and expected its gypsum deposit on the Snake River, Washington County, Idaho, to be in production near the end of 1949. The company will produce agricultural gypsum.[6]

[1] Includes rotary and beehive kilns, grinding-calcining units, and hydrocal cylinders.
[2] Comprises calcining plants in 1947–49: 1 each in Arizona, Connecticut, Florida, Georgia, Indiana, Maryland, Massachusetts, New Hampshire, New Jersey, New Mexico (none in 1947), Oklahoma, Pennsylvania, South Dakota (none in 1949), and Wyoming (none in 1949); 2 each in Colorado, Kansas, Montana, Nevada, Ohio, Utah (3 in 1948–49), and Virginia (3 in 1947).

CONSUMPTION AND USES

New nonfarm housing unit starts during the first half of 1949 were lagging behind 1948, but increased activity during the latter half brought the total starts during 1949 to 1,025,100 compared with 931,300 starts during 1948. This enormous amount of building created a strong demand for such building materials as gypsum lath, wallboard, sheathing, and the various building plasters. Sales to distributors of most gypsum products, however, were moderately lower than in the previous year, indicating that distributors' inventories built up during the winter of 1948–49 were reduced.

Gypsum-Products Plant Developments.—Kaiser Gypsum, a division of Kaiser Industries, Inc., Oakland, Calif., acquired the Redwood City, Calif., gypsum-products plant formerly operated by the Pacific Portland Cement Co. The company plans an extensive moderniza-

tion program, including deep-water unloading facilities for bulk-ore-carrying ships serving the plant with crude gypsum from the company quarry on San Marcos Island, off the coast of Baja, California, Mexico.[7]

The new modern calcining and wallboard plant of Western Gypsum Co., which was put into production in May 1948 at Sigurd, Utah, was described.[8]

Columbia Gypsum Products, Inc., announced its plans for a $200,000 expansion of its facilities at Greenacres, Wash., in the Spokane Valley. New facilities will include a grinding and plaster plant. The company gypsum comes from a deposit at Windermere, British Columbia.[9]

U. S. Gypsum Co. announced plans for a gypsum-products plant at Gerlach, Nev., at the quarry acquired from Pacific Portland Cement Co. in 1948.[10]

An article was published describing operations at the renovated gypsum-products plant of National Gypsum at Savannah, Ga.[11]

[3] Average value per M square feet of wallboard.
[4] Includes partition roof, floor, soffit, shoe, and all other gypsum tiles and planks.
[5] Area of component board and not of finished product.
[6] Per M square feet, f. o. b. producing plant of partition tile only.
[7] Bureau of Mines not at liberty to publish figure.

PRICES

Nearly a third of the crude gypsum produced during 1949 was sold as crude for portland-cement retarder and agricultural uses. The material sold crude for portland-cement retarder had an average value of $3.27 ($3.31 in 1948), and agricultural gypsum had an average value of $4.20 ($3.97 in 1948). The average values of lath, wallboard, sheathing, and laminated board were moderately lower during the year. The average price of base-coat plaster, which is the bulk of building plaster, was virtually unchanged.

FOREIGN TRADE [12]

Imports of crude gypsum from Canada decreased slightly during the year but represented over one-fourth of total domestic supply. Small imports of crude were received from Mexico and Dominican Republic.

Gypsum and gypsum products imported for consumption in the United States, 1945–49

[U. S. Department of Commerce]

Year	Crude (including anhydrite)		Ground		Calcined		Keene's cement		Alabaster manufactures [1] (value)	Other manufactures, n. e. s. (value)	Total value

[1] Effective Jan. 1, 1949, calcined gypsum not separable from crude, crushed, or calcined.
[2] Due to changes in items included in each classification, data are not strictly comparable with earlier years.

TECHNOLOGY

A process for making a low-water-demand, high-strength plaster of Paris was described.[13] The same procedure was independently discovered at nearly the same time in England.[14]

A process for producing a strong plaster by autoclaving ground gypsum in the presence of proteins or soluble fatty acids was patented.[15]

A booklet summarizing the history, manufacture, and development of gypsum plaster and its correct application, physical properties, fire-resistive ratings, and plastering problems and their solutions, was published by the Gypsum Association.[16]

WORLD REVIEW

Australia.—The gypsum industry of South Australia was described.[17]

Canada.—Activity in the Canadian gypsum industry was described in an article.[18] Some of the important producers in Canada are listed as Canadian Gypsum Co., Ltd., with quarries at Wentworth, Hants County, Nova Scotia; National Gypsum (Canada), Ltd., with quarry at Dingwall, Victoria County, Cape Breton Island; Victoria Gypsum Co., Ltd., at Little Narrows, Victoria County; Windsor Plaster Co., Ltd., near Windsor; Connecticut Adamant Gypsum Co., at Cheverie, Hants County; Canadian Gypsum Co., at Hillsborough, New Brunswick; Gypsum, Lime, and Alabastine, Canada, Ltd., with mine at Dingwall, Nova Scotia, and plant at Montreal East. In Ontario there are two producers of gypsum products, Gypsum, Lime & Alabastine, Canada, Ltd., at Caledonia, and Canadian Gypsum Co., Ltd., at Hagersville. In western Canada, Gypsum, Lime & Alabastine, Canada, Ltd., has plants in Winnipeg, Calgary, and New Westminster, gypsum for which is supplied by company quarries at Gypsumville, Manitoba, and Falkland, British Columbia. Western Gypsum Products, Ltd., mines gypsum at Amaranth, Manitoba, which is used in the company plants at Winnipeg and Calgary. Columbia Gypsum Products, Inc., at

[1] In addition to the countries listed gypsum is produced in Angola, Belgian Congo, Ethiopia, Iraq, Jamaica, Luxembourg, Mexico, U. S. S. R., and Yugoslavia, but production data are not available. No estimates for these countries are included in the total.
[2] Data not available; estimate by senior author of chapter included in total.
[3] Rail and river shipments.
[4] Estimate.
[5] Exports.
[6] Bizonal crude production estimates based on the following calcined figures: 1946, 136,500 tons; 1947, 125,600; 1948, 263,822; 1949, 429,400.
[7] Includes Spanish Moroccan production: 1946, 1,219 tons; 1948, 1,829.

Windermere, British Columbia, began mining gypsum which is exported by rail to Spokane, Wash.

India.—The results of an intensive survey of India's reserves of gypsum were reviewed briefly in an article.[19] They reveal that preliminary surveys by the Geological Survey of India indicate conservatively 36,000,000 tons available in Bikaner and Jodhpur in the

[19] Bureau of Mines, Mineral Trade Notes: Vol. 29, No. 5, November 1949, pp. 34-35.

Rajputana region. Additional deposits are known to occur in Nagpur, Mangolad, and Kabas in Jodhpur State. Simur, Kathiawar, Cutch, and certain regions in South India are reported to have gypsum deposits. Gypsum is needed in India in the new Sindri Fertilizer plant and for the manufacture of cement. The Geological Survey of India has been instructed to carry out large-scale explorations to ascertain the quantities available.

Jamaica.—It was reported that gypsum mining had begun near Kingston by the Alcoa Steamship Co. and that most of the production will be used by the Jamaica Bellrock Co., which makes a building panel of gypsum.[20]

Union of South Africa.—The new wallboard plant of Gypsum Industries, Ltd., at Cape Town, South Africa, was described. This plant is reported to have modern calcining and wall board machinery with a rated capacity of 100 tons of calcined gypsum in 24 hours and records indicate that it will turn out 75,000 square feet of board in 24 hours.[21]

Helium

By P. V. Mullins and R. M. Gooding

THE Bureau of Mines produces all helium used by Government agencies and commercial companies in the United States and exports small quantities, chiefly for scientific use. Helium is extracted from helium-bearing natural gases found principally in the southwestern part of the United States. All helium produced in 1949 was extracted at the Bureau of Mines Exell helium plant near Amarillo, Tex.

Helium production in 1949 was 55,165,482 cubic feet, including 5,716,700 cubic feet produced and conserved by underground storage. By comparison, 63,143,513 cubic feet were produced in 1948; 7,794,000 were conserved in underground storage. An important production development in 1949 was a substantial increase in the plant-scale production of high-purity Grade A helium—99.95 percent or higher purity—for better utilization, particularly in inert-arc welding.

The helium demand of the Navy, chiefly for lighter-than-air craft, constituted the largest single demand. Other Federal agencies used significant amounts, however, and commercial demand was a substantial proportion of the total. Helium shipments to Federal agencies in 1949 amounted to 35,133,682 cubic feet, compared with 34,877,490 cubic feet in 1948; non-Federal sales were 16,367,739 cubic feet compared with 16,037,856 cubic feet in 1948.

Reserves.—Helium-bearing natural gas for processing in Bureau plants is available from Government-owned fields and from privately owned fields through processing agreements. The principal Government-owned fields are the Cliffside and the Rattlesnake adjacent to, and available to supply gas to, the Amarillo and Navajo helium plants, respectively. The helium-bearing gas supply for the Exell plant is obtained from the West Panhandle (Tex.) field through a processing agreement with a company transporting gas from that area. The gas is being transported continuously to fuel and other markets, and the contained helium is lost if not extracted concurrently with production from the field.

The Bureau has arrangements whereby helium produced at the Exell plant, and not needed to meet demands, may be transported through a connecting pipeline to the nearby Government-owned Cliffside field and injected therein for underground storage and conservation. In 1949, 5,716,700 cubic feet of helium were produced and conserved in this manner.

Reserves of helium in the Government-owned Cliffside and Rattlesnake fields amount to an estimated 2,800,000,000 cubic feet. Helium reserves in the West Panhandle field, available to the Exell plant, are estimated at 1,500,000,000 cubic feet. Other major reserves of helium-bearing natural gas are known and may become available through purchase by the Government or execution of gas-processing agreements with the owners. No such reserves were acquired in 1949.

The Bureau conducts a continuous survey of natural gas from new field discoveries as a means of locating and obtaining information on additional reserves of helium-bearing gas. There were no important discoveries in this survey during 1949.

Production.—The following table gives helium-production statistics for Government plants in the period 1921–49, inclusive.

Helium production in the United States, 1921–49

Calendar year	Plant	Cubic feet
1921–January 1929	Fort Worth, Tex., plant	46,088,787
1929 (April)–1941	Amarillo, Tex., plant	131,887,380
1942	do	33,252,582
1943	All plants	116,307,437
1944	do	126,933,130
1945	do	94,733,744
1946	Amarillo and Exell, Tex., plants	58,236,385
1947	Exell, Tex., plant	70,297,700
1948	do	63,143,513
1949	do	55,165,482
Total 1921–49		[1] 796,046,140

[1] Includes 83,363,800 cubic feet extracted at the Exell plant from gas from the Channing area and injected into the Cliffside gas reservoir for conservation in calendar years 1945–49.

During 1949, additional plant equipment was installed to provide for continuous large-scale production of high-purity Grade A helium. About 50 percent of the helium produced in 1949 was Grade A purity—99.95 percent or higher—while the balance was about 99.8 percent pure.

During 1930–48, helium produced in Bureau plants was about 98.3 percent pure. Higher purity is obtained by passage of helium through activated charcoal at low temperature.

The Bureau's other helium plants—at Otis, Kans., and at Shiprock, N. Mex. (the Navajo plant)—were continued in standby status.

No information was acquired indicating production of helium in foreign countries in 1949, although small quantities for scientific use may have been produced by extraction from air.

Shipments and Uses.—Demand for helium in 1949 by Federal and non-Federal customers remained near the same high postwar level—about five times that prevailing in prewar years. Legislation and regulations governing helium production and sale, together with limited above-ground storage, normally cause production, shipment, and sales to be nearly identical. These conditions prevailed in 1949 when helium production amounted to 55,165,482 cubic feet, shipments to 51,501,421 cubic feet, and sales to 50,878,573 cubic feet.

In addition to the large demand of the Navy for lighter-than-air craft, the Weather Bureau continued to use helium exclusively in aerological balloons, the Atomic Energy Commission used helium in experimental work, the Army used helium as a fuel propellant in rocket experiments, and other Federal agencies used appreciable quantities for a variety of purposes. The largest and fastest-growing use of helium sold to commercial customers—and an important use among several Government agencies—was application of helium as the shielding "atmosphere" for inert-arc welding of certain metals, notably aluminum, magnesium, and stainless steel.

The following table indicates yearly shipments to Federal and non-Federal consumers of helium for 1941–49, inclusive.

Shipments of helium in the United States, 1941–49 (calendar years), in cubic feet

Calendar year	Shipments to Federal agencies				Sales for non-Federal use			Grand total, shipments
	Navy	Weather Bureau	Army and other Federal agencies	Total	Scientific and commercial	Medical	Total	
1941	11, 187, 440	4, 408, 505	5, 313, 610	20, 909, 555	789. 396	442, 604	1, 232, 000	22, 141, 555
1942	25, 402, 000	5, 090, 715	4, 787, 550	35, 280, 265	359, 085	416, 392	775, 477	36, 055, 742
1943	107, 243, 085	5, 633, 950	2, 434, 695	115, 311, 730	806, 646	513, 282	1, 319, 928	116, 631, 658
1944	111, 075, 569	7, 035, 515	2, 443, 150	120, 554, 234	2, 445, 405	562, 990	3, 008, 395	123, 562, 629
1945	38, 091, 234	8, 010, 210	11, 759, 285	57, 860. 729	2, 362, 028	565, 477	2, 927, 505	60, 788, 234
1946	15, 735, 690	9, 705, 790	9, 287, 750	34, 729, 230	7, 960, 473	1, 233, 817	9, 194, 290	43, 923, 520
1947	26, 511, 005	6, 347, 670	4, 492, 500	37, 351, 175	12, 914, 075	2, 057, 100	14, 971, 175	52, 322, 350
1948	21, 531, 788	6, 478, 931	6, 866, 771	34, 877, 490	13, 735, 645	2, 302, 211	16, 037, 856	50, 915, 346
1949	20, 398, 337	6, 396, 656	8, 338, 689	35, 133, 682	14, 039, 360	2, 328, 379	16, 367, 739	51, 501, 421

Virtually all shipments of helium made from the Exell plant were in tank cars. The remaining helium produced at the Exell plant was transported by pipeline to the Amarillo plant for reshipment by pipeline to the Cliffside field for conservation by injection into the gas reservoir. The Amarillo plant made some helium deliveries by tank car and made all shipments of helium sold in standard compressed gas cylinders. Sixty-eight percent of the helium shipped was in tank cars and 32 percent in cylinders, the latter involving shipment of 68,704 cylinders. All shipping containers for Grade A helium were cleaned internally for specific use in that service. Also, special procedures were developed and used effectively in producing and charging Grade A helium into shipping containers to avoid contamination from oil, water, air, and other foreign substances that might impair utilization of helium for inert-arc welding.

Prices.—An act of Congress approved March 3, 1925, placed responsibility on the Bureau of Mines for conservation, production, and exploitation of helium for national defense. An act of Congress approved September 1, 1937, provided, among other things, that helium not needed by the Government could be produced and sold for commercial use under regulations approved by the President. This act and related regulations provide for commercial sale of helium at a cost that reimburses the Government for the expenses of its production, handling, and sale for that purpose. Prices to non-Federal purchasers of helium in 1949 were the same as in the preceding year. The price per 1,000 cubic feet in 1949 for commercial and scientific use, when shipped from the plant in standard compressed-gas cylinders, was $15 for delivery at the helium plant. Revised regulations governing the commercial sale of helium were approved December 3, 1949, and became effective February 27, 1950. The new price per 1,000 cubic feet of helium is $13.50. When helium is delivered in standard compressed-gas cylinders, a filling service charge of $2 per 1,000 cubic feet is added for this service. No filling service charge is made for helium shipped in tank cars or semitrailers.

Technology.—Under a direct appropriation for the purpose, the Bureau conducts a modest but comprehensive research program at the Amarillo helium plant on all phases of production, shipment, and utilization of helium. During 1949, a substantial part of this research was devoted to work on: (1) Improvements in the use of helium for inert-arc welding, (2) improvement of plant equipment and processing to produce high-purity helium for inert-arc welding, and (3) development of satisfactory means for analyzing high-purity Grade A helium to provide necessary plant control and purity determinations of the final product.

Iron Ore

By Norwood B. Melcher and Jachin M. Forbes

GENERAL SUMMARY

STRATEGIC and economic aspects of the Nation's iron-ore supply continued to receive the attention in 1949 that their importance justified. Results of several years' foreign exploration for new sources of iron ore by industry were made public, and the industry's future course was taking shape. Exploration and development work on iron deposits in the Quebec-Labrador area, Venezuela, and Liberia were progressing, with the positive assurance that these new sources would be put into commercial production as soon as possible. The strategic and economic advantages to be obtained by the construction of the St. Lawrence seaway gained recognition, with iron ore playing a principal role, and it was apparent at the year end that this highly important contribution to the Nation's security and economic health was nearing realization.

Salient Statistics.—Two important factors influenced operation of iron mines in the United States during 1949. The first factor, chronologically, was diminution of demand resulting from the general business recession, which began early in the spring but was not felt at the mines until midsummer. However, it is difficult to evaluate the effects of the recession on iron-ore production because anticipation of the steel strike, the second factor, may have sustained the demand for ore during the summer months. The strike, itself, canceled

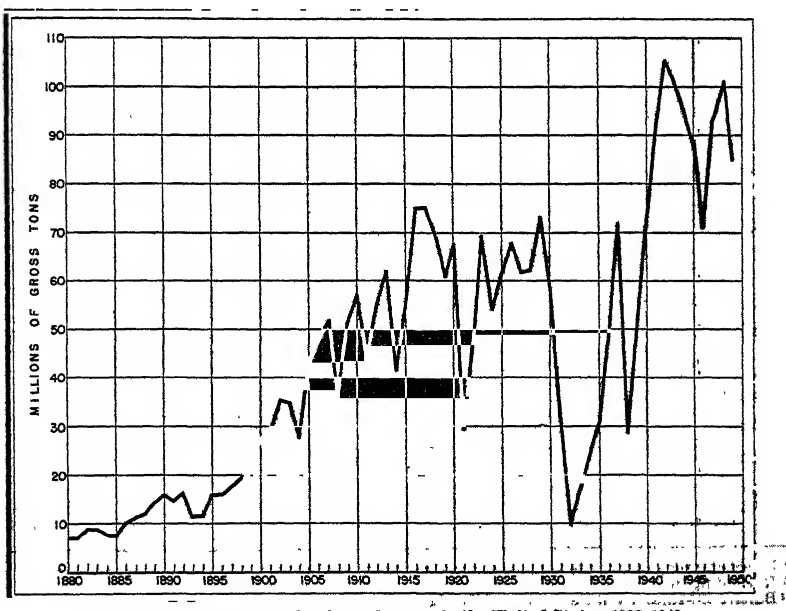

FIGURE 1.—Trends in production of iron ore in the United States, 1880–1949.

approximately 6 weeks' production and shipments during the latter part of the Great Lakes shipping season.

Domestic crude-ore production totaled 104,850,736 gross tons in 1949 compared with 126,225,172 tons in 1948, a decrease of 17 percent. Production of usable ore was off 16 percent to 84,937,447 tons, lowest since 1946, but higher than any prewar year. Usable ore includes direct-shipping ore (mine product requiring no treatment), washed ore, concentrates, sinter, and byproduct pyrites cinder and sinter.

Imports of iron ore increased again in 1949. The 21-percent increase over 1948, a total of 7,402,157 tons, established a new record and raised the proportion of imported ore to 8 percent of the supply, compared with 6 percent in 1948. Leading sources were Chile, Sweden, and Canada, supplying 35, 28, and 22 percent, respectively. Canada increased shipments to this country in 1949 by 63 percent and Sweden by 51 percent. Canada expects to up production from its Steep Rock district in 1950, but the Labrador-Quebec ores are not expected to be in commercial production for several years. Swedish imports are related to current United States economic conditions and may increase or decrease.

RESERVES

Reserves of commercial[1] iron ore in the United States on January 1, 1951

[U. S. Geological Survey]

District	Iron, percent (approximate)	Gross tons (measured, indicated, and inferred)
Lake Superior	51.5	3,024,658,000
Northeastern	60	1,110,000,000
Southeastern	35	1,626,700,000
Southern	45	64,200,000
Western	50	610,000,000
Total		6,435,558,000

[1] Material considered usable under present economic and technologic conditions.

PRODUCTION AND SHIPMENTS

Domestic iron-ore mines produced crude ore totaling 104,850,736 gross tons and shipped 104,477,495 tons in 1949, decreases of 17 percent from 1948 in both instances. Of the 1949 shipments, 39 percent went to beneficiating plants and 61 percent went direct to consumers, as in 1948. From the crude ores shipped to beneficiating plants, 16,412,639 tons of concentrates and 4,018,794 tons of sinter were produced. In addition, 535,998 tons of byproduct ore in the form of cinder and sinter were produced by the pyrites industry during 1949. The ore from which this byproduct was produced is not included in the crude ore totals given above. In all, 84,937,447 gross tons of usable iron ore, including byproduct, were produced at mines and mills in 1949, a 16-percent decrease from 1948. Of this quantity, 63,970,016 tons were shipped directly to consumers without beneficiation.

The output in 1949, excluding byproduct material noted above, came from 221 mines, of which 36 mined over 1,000,000 tons of crude ore each. Minnesota, with 55,861,542 tons, and Michigan, second-largest producer, with 11,199,024 tons, supplied 66 and 13 percent, respectively, of the total usable ore in 1949. These two States and Wisconsin, with 1,433,557 tons, constitute the Lake Superior district, which supplied 81 percent of the domestic output.

Open-pit mines provided 74.5 percent of the crude ore mined in 1949 compared with 78.4 percent in 1948. Distribution, percentagewise, of crude-ore production by districts indicates little change from 1948: Less than 0.5 percent in the Southeastern and Northeastern districts, 1 percent gain in the Lake Superior district, and 1 percent decline in the Western district.

[1] Excludes an undetermined number of small pits. Output of these pits included in tonnage given.
[2] Approximate figure.

Shipments of usable ore from mines and mills totaled 84,687,275 gross tons in 1949, a 16-percent decrease from 1948. Of this quantity, 63,492,932 tons (75 percent) were direct-shipping ore for use in iron and steel furnaces. Total shipments also include 40,152 tons of ore for cement manufacture, 6,145 tons for paint, and 57,800 tons for miscellaneous purposes (including use as heavy mediums for ore beneficiation). Shipments of byproduct ore for use in iron and steel included in the total shipments amounted to 512,876 tons in 1949, valued at $3,878,700.

[1] Produced in Fillmore County—not in the true Lake Superior district.
[2] Approximate figure.

PRINCIPAL MINES

An accompanying table lists in descending order, with pertinent details, the iron mines of the United States that produced over 500,000 gross tons of crude ore each in 1949. The order of listing is based on ore tonnage, not iron content of product; thus mines producing low-grade crude ore that requires concentration are considered comparable in size to mines producing similar tonnages of direct-shipping ore.

Thirty-six mines, each producing more than 1,000,000 tons of crude ore, supplied 57 percent of the United States output in 1949. Of these, 24 are in Minnesota, 5 in Alabama, 3 in New York, and 1 each in Michigan, Pennsylvania, Texas, and Utah; 28 were open-pit mines, 6 were underground, and 2 combined operations. Except for 4 mines that produced magnetite, 1 producing semialtered magnetite, and 2 producing brown ore, all of the million-ton mines produced hematite in 1949. In 1948, 36 mines producing more than 1,000,000 gross tons of crude ore each supplied 60 percent of the total domestic output.

Twenty-eight mines producing 500,000 to 1,000,000 gross tons of crude ore each supplied 17 percent of the United States total output in 1949. Of these, 14 are in Minnesota, 5 in Michigan, 2 each in Alabama and Utah, and 1 each in California, New Jersey, New York, Wisconsin, and Wyoming. Seventy-four percent of the total domestic output of crude ore came from the 64 mines listed in the accompanying table.

SINTER

Domestic sintering plants in 1949 used 11,869,127 gross tons of iron ore, 4,230,262 tons of flue dust, 559,051 tons of pyrites cinder, 7,413 tons of manganiferous ore, and 409,852 tons of mill cinder and roll scale to produce 15,374,026 gross tons of sinter, a conversion yield of 90 percent.

Sinter production in 1949 came from plants at mines, blast-furnace plants, and custom mills. Of the sinter produced in the United States, 26 percent was made at mine plants in 5 States, and 74 percent was produced at blast-furnace plants and custom mills in 14 States.

Production and consumption of sinter in the United States in 1949, by States, in gross tons

State	Sinter produced	Sinter consumed—	
		In blast furnaces	In steel furnaces
Alabama	1,343,313	1,482,232	82,999

Total	15,374,026	12,738,457	939,059

REVIEW OF LAKE SUPERIOR DISTRICT

Production and Shipments.—Usable iron ore produced from mines and mills in the Lake Superior district totaled 68,391,965 gross tons in 1949. The decline (17 percent) from the high total of 1948 was attributable to the same factors affecting the United States iron-ore industry mentioned in the General Summary. The district—which includes the Marquette, Menominee, Gogebic, Vermilion, Mesabi, and Cuyuna ranges—supplied 81 percent of all domestic iron ore, with 62 percent supplied by the Mesabi range alone. In addition, 102,158 tons of brown-ore concentrates were produced and shipped from Fillmore County, southern Minnesota, which is not considered part of the true Lake Superior district, and 862,361 tons of ore containing (natural) more than 5 percent manganese (all from Minnesota) were produced. Including these last tonnages, output for the district, all grades, totaled 69,356,484 tons. Shipments from the district totaled 69,226,837 tons, of which 69,124,679 tons (including 884,109 tons of manganiferous ore) came from the six ranges and 102,158 tons from Fillmore County, Minn.

Production and shipments from Canadian mines in the Lake Superior district are not included in the above statistics. Shipments from these mines in 1949 totaled 1,796,000 tons. Of this quantity,

662,000 tons came from the Helen mine in the Michipicoten district, and 1,134,000 tons were shipped from the Steep Rock mine in the Steep Rock district. The Lake Superior Iron Ore Association reported 67,800,229 gross tons of iron and manganiferous ores shipped to upper Lake ports from United States mines in 1949, or 17 percent below 1948. All-rail shipments totaled 1,428,416 tons in 1949 compared with 1,745,397 tons in 1948.

The 1949 Lake shipping season opened March 27 and closed December 4, several days longer than the average season, although approximately 43 days of shipping were lost during the steel strike. The season opened strongly, and shipping continued at a high rate until reduced consumption by furnaces made itself felt about midsummer. The entire decrease from the 1948 total occurred in the latter part of the season, the bulk of the tonnage being lost during the strike. Had the strike been averted, a record stockpile of ore might have accumulated at lower Lake ports and consumers' yards.

Iron mines in the Spring Valley area in Fillmore County, southern Minnesota, produce brown-ore concentrates from a bog type of limonite of different origin and mineral character than the Lake Superior ores. Washing is the principal means of beneficiation, and all the concentrates are shipped by rail to Granite City, Ill.

Iron ore produced in the Lake Superior district, 1854–1949, by ranges, in gross tons

[Exclusive after 1905 of ore containing 5 percent or more manganese]

Year	Marquette	Menominee	Gogebic	Vermilion	Mesabi	Cuyuna	Total
1854–1944	229,773,915	205,736,670	242,702,380	75,704,578	1,376,030,818	32,807,310	2,162,755,671

Total	252,188,396	224,023,187	266,219,561	82,851,296	1,656,460,550	41,929,278	2,523,672,268

Technologic Developments.—As in recent years, research efforts in 1949 were directed toward economic beneficiation of low-grade ores to a product acceptable for blast-furnace use. Current beneficiation methods have been reviewed.[1,2] Ore types at present capable of profitable beneficiation include "ore fines," which are high enough in iron content but require sintering or pelletizing to suitable physical character; "wash ore," which requires only simple crushing, sizing and washing, and jig or heavy-medium ores which require means to remove rocks of varying sizes. Taconite, the hard, iron-bearing rock that is receiving the most attention at research laboratories, cannot yet be included with ores profitably beneficiated. Progress is being made, and in 1949 more than 15,000 tons were produced in the preliminary plant of the Erie Mining Co. near Aurora, Minn. The flow sheet used in this plant was published.[3]

[3] Engineering and Mining Journal, Taconite Flow Sheet at Aurora Is Disclosed: Vol. 150, No. 11, November 1949, p. 110.

Skillings' Mining Review, Erie Mining Co. Continues Taconite Research on Mesabi Iron Ranges: Vol. 38, No. 28, Oct. 22, 1949, pp. 1–2.

Improvements in underground methods are exemplified by plans of the Cleveland-Cliffs Iron Mining Co. to install a belt conveyor for lifting ore in the Cambria-Jackson mine at Negaunee, Mich. This conveyor will accomplish a vertical lift of 110 feet with a belt 594 feet long on a 15° incline. Increased mechanization is proving the best means of reducing the costs of underground mining.

Analyses.—The following table shows the average analyses of all ore shipped from the Lake Superior district during the past 5 years. Again, in 1949, slightly increased percentages of silica, phosphorus, and manganese are noted, with gradual decline of average iron content.

Average analyses of total tonnages (bill-of-lading weights) of all grades of iron ore from all ranges of Lake Superior district, 1945–49

[Lake Superior Iron Ore Association]

Year	Gross tons	Content (natural), percent				
		Iron	Phosphorus	Silica	Manganese	Moisture
1945	75, 206, 781	51. 69	0. 089	8. 52	0. 72	10. 96
1946	58, 975, 188	51. 32	. 087	8. 83	. 74	11. 22
1947	77, 210, 278	50. 91	. 093	9. 09	. 75	11. 28
1948	82, 655, 757	50. 49	. 093	9. 30	. 76	11. 35
1949	68, 531, 664	50. 39	. 096	9. 72	. 78	11. 12

Reserves.—The following tables show reserves of iron ore in Michigan and Minnesota by ranges. It should be borne in mind that these data represent only taxable and State-owned reserves and do not represent the total that may be expected to become available. Tonnages are added to the reserve figures each year, and undoubtedly eventual production in the Lake Superior district will greatly exceed that indicated by present reserve tonnages.

Iron-ore reserves in Michigan, Jan. 1, 1946–50, in gross tons

MINING BY STATES

Alabama.—Production of usable iron ore in Alabama, the third largest producing State, decreased only 9 percent below 1948, compared with 18 percent in Minnesota and 15 percent in Michigan. Output of red ore, virtually all from underground mines, fell 10 percent, while that of brown, all from open-pit mines, increased 1 percent. The active underground red-ore or hematite mines in Alabama are in Jefferson County near Birmingham. Operations extend as much as 2 miles down the incline of the Red Mountain iron formation, which outcrops below Birmingham and dips southeast. Ore from the southwest end of operations runs high in lime and grades down in lime and up in silica and alumina to the northeast. Blending is necessary to permit use of the acid ores. The Tennessee Coal, Iron & Railroad Co., the largest operator, shipped red ore from its Red Mountain mines—the Muscoda, Ishkooda, and Wenonah groups. After crushing and blending, four-fifths of this ore was shipped direct, and the balance was sintered. Woodward Iron Co. shipped ore direct from its Pyne, Songo, and Red Ore underground mines. Sloss-Sheffield Steel & Iron Co. shipped red hematite from its Ruffner and Sloss underground mines and brown-ore concentrates from its Russellville No. 14 open-pit mine. Republic Steel Corp. shipped direct from its Edwards mine (underground) and sintered the production of its Spaulding mine (underground and open pit). Approximately 20 non-consuming operators shipped brown-ore concentrates from various open-pit mines in 8 counties. The largest of these was the Shook & Fletcher Supply Co. of Birmingham. The weighted average grade of hematite shipped from Alabama mines and mills during 1949 was 35.77 percent Fe (natural).

All of the brown ore produced in Alabama in 1949 was wash concentrate from open-pit mines.

California.—The Eagle Mountain mine of the Kaiser Steel Corp. operated full time in 1949, with all its production going to the Fontana furnaces. The Vulcan mine in San Bernardino County did not operate but shipped 55,883 tons from stocks.

Georgia.—Iron-ore production of Georgia consisted entirely of washed brown-ore concentrates from open-pit mines in the northwest portion of the State. Bartow, Cherokee, and Polk were the only counties reporting production in 1949. The Hodge Mining Co., Cartersville, Ga., was the largest producer in 1949.

Michigan and Minnesota.—See Review of Lake Superior district.

Missouri.—The Iron Mountain open-pit mine in St. Francois County, operated by the Ozark Ore Co., produced hematite concentrates averaging 51.97 percent Fe (natural). Beneficiation consisted of crushing and jigging. Brown ore was shipped from various small surface operations in Wayne County by Doane and Ives of Poplar Bluff, Mo.

Nevada.—The only production of iron ore reported from Nevada in 1949 was that of Segerstrom & Heizer, Lovelock, Nev.

New Jersey.—The Oxford and Wharton districts of New Jersey were the only producers in 1949. In the Oxford district, the Alan Wood Steel Co., produced magnetite concentrates from the Washington mine. In the Wharton district, the Alan Wood Steel Co. operated

the Scrub Oaks mine, the Richard Ore Co. the Richard mine, and the Warren Pipe & Foundry Corp. the Mount Hope mine. Some lump and coarse ore was shipped direct to steel furnaces, but the greater part of shipments consisted of magnetite concentrates beneficiated by magnetic and gravity methods. A small amount of New Jersey ore was employed in making cement and for miscellaneous uses. The average iron content in 1949 was 63 percent.

[1] Excludes undetermined number of small pits. Estimated output of these mines included in tonnage given.

New York.—Operations in the Adirondack district of upper New York State included underground mines of the Republic Steel Corp.—the New Bed-Harmony-Old Bed group and Fisher Hill at Mineville in Essex County, and the Chateaugay mine at Lyon Mountain, Clinton County; Hanna Coal & Ore Corp. Clifton mine at Degrasse, St. Lawrence County; Jones & Laughlin Ore Co. Benson mine at Star Lake, St. Lawrence County; and the National Lead Co. MacIntyre development at Tahawus, Essex County. In addition, a small quantity of Clinton hematite was mined in Oneida County for use in pigments.

The Adirondack ores are magnetite with associated nonmagnetic martite in the Star Lake area. Titaniferous magnetite is mined from

the MacIntyre development. Shipments consisted mainly of sintered concentrates (in 1949, 82 percent), only 13 percent of the 1949 concentrates being shipped without sintering. Of these unsintered concentrates, 79 percent was used to make iron and steel; and other uses were as components of heavy mediums, refractories, and cement.

Pennsylvania.—Bethlehem Steel Corp. produced magnetite from underground and open-pit mines at Cornwall, Pa., during 1949. All of the mine output was concentrated, and two-thirds of the concentrates were sintered at Lebanon.

Texas.—The Lone Star Steel Co., principal producer, mined brown ore from open pits in the Daingerfield area, Morris County. Beneficiation consisted of washing, calcining, and sintering. Sheffield Steel Co. operated two open-pit brown-ore mines: The North Basin at Linden, Cass County, and the Mount Haven at Jacksonville, Cherokee County. The Valencia Iron & Chemical Co. operated surface mines near Rusk, Cherokee County.

Utah.—The Cedar City area in Iron County produced a direct-shipping semialtered magnetite averaging 53.3 percent Fe in 1949. The Columbia Iron Mining Co. worked the Iron Mountain mine; Colorado Fuel & Iron Corp., the Blowout and the Duncan mines; Utah Construction Co., the Excelsior; and Helene E. Beatty, the Great Western. Ore from this area serves three iron- and steel-making centers—Geneva and Provo in Utah; Pueblo, Colo.; and Fontana, Calif.

Virginia.—A small quantity of iron ore was mined by open-pit methods in Pulaski County during 1949 for use as pigment.

Wisconsin.—See Review of Lake Superior district.

Wyoming.—Colorado Fuel & Iron Corp. produced direct-shipping hematite from underground operations at the Sunrise mine in the Hartville district, Platte County; shipments averaged 49 percent Fe (natural).

CONSUMPTION

Consumers of iron ore reported 89,218,498 gross tons used in 1949, a decrease of 11 percent from 1948. Distribution by types of consumers indicates no change from 1948: Blast furnaces 82 percent, sintering plants 13 percent, steel furnaces 4 percent, and ferro-alloy furnaces, cement plants, pigments, and other items 1 percent. In addition to the iron ore used, blast furnaces consumed 12,738,457 tons and steel furnaces 939,059 tons of sinter.

STOCKS

Stocks of usable iron ore at mines on December 31, 1949, were 15 percent below 1948. Of the quantity in stockpiles, 38 percent was at mines in Michigan, 29 percent in Minnesota, and 24 percent in New York. Including Wisconsin, the Lake Superior district held 69 percent of the total stocks at the end of the year. Stocks of crude ore at mines totaled 3,335,095 gross tons on December 31, 1949, compared with 4,662,648 tons at the end of 1948.

Stocks of iron ore, including sinter, at consuming plants totaled 37,023,767 gross tons on December 31, 1949, compared with 37,144,933 tons at the end of 1948.

Consumption of iron ore in the United States in 1949, by States and uses, in gross tons

Stocks at Lake Erie Ports.—On December 1, 1949, 4 days before the last ship of the season was loaded at an upper Lake port, the Lake Superior Iron Ore Association reported 6,938,595 tons of iron ore on Lake Erie docks compared with 5,689,828 in 1948. At the opening of the 1950 season (May 1, 1950), 3,065,827 tons of ore were in stock at these ports, compared with 2,033,169 tons on May 1, 1949. Thus, withdrawals from stock during the 5-month period 1949–50 were 6 percent more than during the previous year.

PRICES[4]

Value at Mine.—The average value per gross ton of iron ore f. o. b. mines and mills was $4.50 in 1949 compared with $3.91 in 1948 and $3.44 in 1947, an increase of 31 percent in 3 years. However, during the period 1939–49, iron ore has increased 56 percent in value, while

[4] For an explanation of the factors affecting the price of iron ore, see Minerals Yearbook, 1948, p. 647.

the wholesale price index [5] for all commodities increased 101 percent.

The accompanying table gives the average value at mines of the different classes of iron ore in 1949 for each of the producing States or groups of States, except where there are fewer than three shippers of a certain class of ore in a State and permission has not been given to publish the value. These data are taken directly from statements of producers and probably represent the commercial selling prices only approximately. In general, the delivered cost less transportation costs to the consuming plants is given. In the Lake Superior district the mine value is the Lake Erie price less freight from mines to lower Lake ports. This value appears to be applied also to ore that is not sold on the open market.

Average value per gross ton of iron ore at mines in the United States, 1948–49

Prices of Lake Superior Iron Ore.—Lake Erie base prices for Lake Superior iron ores remained throughout the season at the level made effective December 30, 1948, for the 1949 season. This level specified Old Range Bessemer at \$7.60; Old Range non-Bessemer, \$7.45; Mesabi Bessemer, \$7.35; Mesabi non-Bessemer, \$7.20, and High-Phosphorus, \$7.20 per gross ton. Prices for 1950 had not been announced at the end of the year.

Lake Erie prices are used as a basis for negotiation since few ores match the specifications listed. These prices are for ore delivered at lower Lake ports, carrying 51.5 percent natural iron content with 0.045 percent (max.) phosphorus (dry), for Bessemer grades and up to 0.18 percent phosphorus, for non-Bessemer grades. Above 0.18 percent, the ores are classed as High-Phosphorus. Premiums and penalties are applied for variations in the analyses and physical structure.

[5] U. S. Department of Labor Index, All Commodities.

Freight Rates.—Upper Lake rail freight rates remained unchanged in the 1949 season at $1.05 per gross ton from Minnesota ranges to upper Lake ports, $0.92 for rail movement, and $0.13 for dock loading. Vessel rates increased $0.12 per ton during 1949, of which $0.10 was a freight-rate increase effective at the beginning of the season and $0.02 was in dock handling charges (hold to rail of the vessel, $0.018 effective January 11 and $0.0092 September 1, 1949). Vessel rates totaled $1.45 per gross ton. Lower Lake rail freight rates increased 17 cents to $1.89 per gross ton to the Pittsburgh-Wheeling area. Thus, total transportation charges from the Mesabi range to Pittsburgh were $4.39 per gross ton at the end of the 1949 season. Average value of ore before shipment from the Mesabi range was $4.24 per ton, making the indicated average value of Mesabi ore in Pittsburgh yards $8.63 per ton.

FOREIGN TRADE [6]

The following tables list the country, tonnage, and value of iron ore imported and exported during 1947–49. There were no important new sources in 1949, although the import totals were again record-high. Nearly all of the increase was supplied by Sweden and Canada, while Chile virtually equaled its 1948 shipments. Canada, however, again received more ore from the United States than it exported to the United States. Japan was the only other country receiving an important tonnage of United States iron ore.

[1] Revised figure.

BENEFICIATION

Each year, the percentage of iron-ore shipments that receives treatment, designed to make a more desirable blast-furnace feed, climbs higher. During the 10-year period 1930–39 the percentage fluctuated from a low of 7.6 percent in 1932 to a high of 18.8 percent in 1936, while the over-all change was from 16.3 to 17.2 percent. Since 1940 the percentage has climbed steadily to 24.5 percent in 1949. Thus, the importance of ore treatment increases, and industry is recognizing this fact by allotting larger funds to beneficiation research.

Crude iron ore is divided into three groups. The first group includes the diminishing ores suitable for direct blast-furnace feed as mined, usable with only a primary crushing operation. The second group formerly included only those ores that were made acceptable by hand picking or simply washing away loose gangue material. In recent years, however, this second group has been expanded to include ores that require beneficiation by more complex methods. These ores have their iron minerals bonded to the gangue minerals in small particles, which must be liberated by grinding before they can be separated. The relative size of the iron particles grades downward, and economic factors control the lower limit of the particle size that may be liberated. After liberation, separation is accomplished by jigs in the case of larger particles, magnetic devices when the ore is magnetite, and heavy-medium or gravity methods for the finer particles. The concentrated product must then be sintered or pelletized into a suitably large and porous blast-furnace feed. Group 3 may not yet be truly classed as an ore, since it refers to taconite, which has not yet achieved economic beneficiation. Nevertheless, industrial determination and economic necessity assure a place for taconite concentrates in the near future. Trade literature since World War II offered profuse information on taconite beneficiation, and preliminary research indicates that the iron formation bearing magnetite particles will be first to achieve economic beneficiation. Reserves of this type

of taconite are estimated to be adequate to produce 1.7 billion [7] tons of concentrates.

Iron ore shipped from mines in the United States, 1925–29 (average) and 1930–49, in gross tons, and percentage of beneficiated ore compared to total shipped

EMPLOYMENT

Preliminary employment figures for 1949 indicate a 2-percent increase over 1948 in the number of workers in iron mines and mills and a 13-percent decrease in man-hours recorded. This divergence is directly attributable to the steel strike. The average number employed is estimated at 31,100 men working 60,600,000 man-hours to produce 85,263,810 tons of usable iron and manganiferous ores, an average of 1.407 tons per man-hour. This compares with 1.462 tons per man-hour in 1948 and 1.442 tons in 1947. A 4-percent increase in the proportion of ore mined underground in 1949 partly accounts for the decrease in ore mined per man-hour. The above data and the table that follows include, in the Lake Superior district, manganiferous ore, which is considered by the trade a special grade of iron ore.

WORLD REVIEW

The accompanying table shows world production of iron ore, by countries, in recent years.

CANADA [8]

British Columbia.—A small shipment to electric furnaces at Wenatchee, Wash., marks the first iron-ore production from this Province in 50 years.[9] The ore was from magnetite deposits at Upper Quemsaim Lake, Vancouver Island. The operator was Coast Iron Co., Ltd. This company was recently organized by Privateer Mine, Ltd., and Frith-Kershaw, Ltd., and expects to operate on an export basis.[10]

Newfoundland.—The Wabana hematite ores outcropping on Bell Island, Newfoundland, are a bedded deposit capable of greatly expanded production. Certain difficulties, however, present themselves. Aside

[1] In addition to countries listed, Bulgaria, Burma, Egypt, Eritrea, French West Africa, Greece, Madagascar, Portugal, South-West Africa, and Yugoslavia report production of iron ore in past years, but quantity produced is believed insufficient to affect estimate of world total, except for Yugoslavia for which estimate has been included in the total.
[2] Data not available; estimate by author of chapter included in total.
[3] Production of Tofo mines.
[4] Estimate.
[5] Including Moselle (Lorraine).
[6] Exclusive of manganiferous iron ore carrying 12 to 30 percent manganese.
[7] Includes Eastern Upper Silesia.
[8] Excluding Soviet zone.
[9] Data represent Trianon Hungary after October 1944.
[10] January to June, inclusive. [11] January to September, inclusive.
[12] U. S. S. R. in Asia included with U. S. S. R. in Europe.
[13] Exclusive of bog ore, which is used mainly for purification of gas.
[14] Production of National Resources Commission only.
[15] Includes iron sand production as follows: 1943–44, 427,000 tons; 1944–45, 858,782 tons; 1945–46, 235,094 tons; 1946, 10,472 tons; 1947, 3,772 tons; 1948, 2,583 tons; 1949, 23,724 tons.
[16] Fiscal year ended Mar. 31 of year following that stated.

from the fact that workings extend over 2 miles under Conception Bay, the ore is high in phosphorus and does not lend itself to large use in United States furnaces (a small tonnage was consumed in the blast furnace at Everett, Mass., in 1949).

Of the 1,480,000 gross tons shipped in 1949, 50 percent went to furnaces at Sydney, Nova Scotia, 48 percent to the United Kingdom, and 2 percent to the United States. Operations of Wabana mines were described in some detail.[11]

Ontario.—Shipments from Steep Rock Mines in 1949 were 1,134,261 gross tons compared with 686,385 tons in 1948, an increase of 65 percent. All output was from the Errington mine (formerly called "B" pit) and was classified into 1,096,763 tons standard grade and 37,498 tons of high-sulfur ore suitable for sintering-plant consumption. The standard ore is divided further into Seine River grade for blast furnaces and Steep Rock open-hearth lump grade.

The Errington deposit is now known to be 3,000 feet long, and the ore body has been drilled to a depth of 4,000 feet. Although several more years of surface operations are expected, the company has announced intentions to begin underground operations in 1950. Plans call for a vertical shaft to be sunk an initial depth of 1,200 feet, 2,000 feet from the open pit. From this shaft, three levels beneath the open pit will be developed. The lower level will be used for pumping until subsequent lower levels take over this operation, leaving the higher levels for mining. The objective of the underground plan is to attain a production of 1,000,000 tons annually by 1955, when the open pit will be inoperable.

Production from the Hogarth mine ("A" ore body) is expected to begin in 1953. Financial arrangements have been completed, and a contract let for the stripping of lake silt. Full production is not expected until 1955.

The "C" ore body has been leased to the Inland Steel Co., and development work begun. The geology of the Steep Rock lake area was described in 1949.[12]

Siderite deposits in the Michipicoten district are high grade, and reserves are extensive. However, the only producer in 1949 was the Helen mine, operated by Algoma Ore Properties, Ltd., a subsidiary of Algoma Steel Corp., Ltd. The product is calcined and sintered before blending with Lake Superior hematites. Mine shipments in 1949 were 662,000 tons of sinter, although the plant has a capacity of 1,000,000 tons per year.

Additional crude-ore production is expected in 1950 from the Victoria open pit and an underground operation on the same ore body. Development continues on the Siderite Hill deposit, discovered late in 1948, and it is reported that this property will permit surface mining.

The Ruth and Lucy properties are under lease to Jones & Laughlin Steel Corp., but development work has not yet begun.

A recent review[13] points out the geologic similarity of Eastern Ontario to the magnetite-producing areas of the Adirondacks in New

[12] Hicks, W. S., Geology of the Iron Deposits of Steep Rock Iron Mines, Ltd.: The PreCambrian, vol. 23, No. 5, May 1950, pp. 8–13.
[13] Bonham, W. M., Magnetite in Eastern Ontario: Canadian Min. Jour., vol. 70, No. 8, August 1949, pp. 57–60.

York. Evidence is presented to show the possibility of producing magnetite concentrates on a scale comparable to that of New York.

Quebec.—Noranda Mines, Ltd., continued research and development on the extensive reserves of pyritic iron ore in Quebec.

Quebec-Labrador.—Progress in the development of the northern hematite deposits was highlighted by the announcement that plans had been completed for constructing the railroad from Seven Islands to the deposit, a distance of 350 miles. Proved reserves at the end of 1949 were 358,000,000 tons, of which 205,000,000 were Bessemer grade, 109,000,000 were non-Bessemer, and 44,000,000 manganiferous (7.87 percent Mn). Due to the large sums involved, financial arrangements are complex. Hollinger-Hanna, Ltd., is the central company, with various combines organized to aid in bringing deposits into production. The Iron Ore Co. of Canada, Ltd., is composed of six United States companies, and its duties include financing to the point of production and then marketing the ore. Mining operations will be conducted by the central company, Hollinger-Hanna, Ltd., while continued exploration will be done by either or both subsidiary companies, Labrador Mining & Exploration Co., Ltd., and Hollinger North Shore Exploration Co. Other subsidiary companies include: Hollinger Ungava Transport, Ltd.; Ungava Power Co., Ltd.; and Quebec North Shore & Labrador Railway Co., Ltd.[14]

Reports emphasize that proved reserve tonnages do not indicate the ultimate extent of the ore that will be available. Only enough reserves have been proved to justify the necessarily large capital outlay. At this point, there is no doubt that enough high-grade ore is available to permit surface operations for many years. The principal difficulty remaining to be overcome is the problem of transportation low enough in cost to permit economic production of 10,000,000 tons annually. This figure is judged to be the minimum that will support economic operations.

OTHER COUNTRIES

Argentina.—Exploration has begun of the iron-ore deposits near Sierra Grande between Antonio Oeste and Puerto Madryn in the Territory of Rio Negro, Argentina. The deposits are conveniently located only 22 miles from the coast and are said to be both extensive and rich.[15]

Australia.—Government agencies are making a broad survey for new Australian mineral deposits, including iron ore and its supporting raw minerals. Modern geophysical methods are being used.[16]

Austria.—The Oesterreich-Alpine Montangesellschaft, an iron-mining company producing Styrian ore concentrates, has, with the assistance of the Economic Cooperation Administration, incorporated modern beneficiation practices at its Erzberg mine. Production does not yet meet domestic ore requirements, but substantial increases were made in 1949.[17] The ore is low grade, running only

about 25 percent iron as mined. However, it is manganiferous and easily beneficiated.[18]

Ceylon.—Iron ore of lateritic origin is available from deposits that have been mined in the past on the island of Ceylon. Plans have been announced to build a small-scale iron furnace to supply local needs.[19]

Chile.—An agreement signed recently by Bethlehem Chile Iron Mines and Cia de Acero del Pacifico calls [20] for Bethlehem to supply iron ore to Pacifico's furnaces at Corral for 20 years. Included also are plans for exploiting the El Romeral deposit near La Serena.

Cuba.—The Mayari Deposit was the only Cuban iron ore producer in 1949.

Iron ore shipped from mines in the Province of Oriente, Cuba, 1884–1949, in gross tons

Year	Juragua, Daiquiri, and Estancia (hematite and magnetite)	Sigua (hematite)	Mayari (brown ore)	Guama (hematite)	El Cuero (hematite)	Total
1884–1947	22,740,281	20,438	4,045,133	41,241	903,103	27,750,196
1948			34,025			34,025
1949			11,446			11,446
Total	22,740,281	20,438	4,090,604	41,241	903,103	27,795,667

Czechoslovakia.—The Medlov and Sternberg iron mines in Czechoslovakia plan [21] to increase capacity to offset the loss of imports from Yugoslavia. An iron-ore shortage in this country is partly responsible for the poor showing of the 2-year plan to increase steel output.

Dominican Republic.—Rich iron deposits reported [22] to contain 43 million tons of 67 percent iron have been discovered in the Duarte Province of the Dominican Republic. As in many other small countries, hope is entertained that a small domestic steel industry may be established on the strength of domestic mineral resources.

Egypt.—The Mines and Quarries Administration of the Egyptian Government reports [23] discovery of an iron-ore deposit near the El Quseir (formerly Kosseir) region and another at Wadi Karim, west of El Quseir. The deposits are only about 18 miles from the Red Sea.

Finland.—While Finland's iron-ore requirements are being met [24] by imports, principally from Sweden, efforts are being made to develop an important deposit of titaniferous magnetite near Lake Oulujärvi in the central part of the country. The mine is owned and operated on a pilot-plant scale by the Finnish Government.

France.—The French Iron Ore Mines Federation reports [25] that the mere addition of manpower will not increase production from iron mines in the Lorraine Basin. Consequently, rising costs are to be met by plans for increased mechanization. It is believed that the technical advantages obtained will permit easier labor relations as

well as increased production owing to the provision of more desirable jobs for the workers.

Liberia.—One of the outstanding developments in the iron-ore industry during 1949 was announced by the Republic Steel Co. in March.[26] Republic has bought an interest in the Liberian Mining Co., Ltd., which was organized by L. K. Christie to develop the Bomi Hills iron ore deposit. Company engineers and geologists from the United States Geological Survey proved that iron deposits in the highlands of the northeastern part of the country contained enough high-grade ore to warrant exploitation. Additional financial aid was obtained from the Export-Import Bank of Washington, D. C., in May 1949.[27]

Reserves are estimated at over 20 million tons of open-hearth-grade ore with additional tonnages of blast-furnace grade.[28] The deposit selected for exploitation is at Bomi Hills, 45 miles northeast of the modern port and capital, Monrovia. Open-pit operations will start on an ore face outcropping 150 feet high and half a mile long, and a railway is under construction between the port and the deposit. Republic has first option on the product, with surplus to be sold on the world market. Initial production will approximate 1,000,000 tons per year.

Malaya.—Exports from mines in Malaya have been small in recent years. However, large reserves of high-grade iron ore exist, and the Japanese market promises to aid in developing these deposits. Plans call for export of 600,000 tons from the Bukit Besi mine as soon as shipping is available for transport to Japan.[29]

New Zealand.—Experimental production of pig iron from the titaniferous sands distributed widely along the west beaches of New Zealand was achieved in 1949.[31] The sands contain, in addition to iron, recoverable amounts of titanium and vanadium. Electric furnaces have proved most successful metallurgically for separating these elements, but at present little encouragement can be found for electricity as a source of power.

Norway.—The Sydvaranger iron mines in northeastern Norway are scheduled [30] to be reactivated under a project approved by the Economic Cooperation Administration. These mines were in operation from 1910 until they were destroyed by the German Army in 1944. This product is a high-grade magnetite concentrate, in great demand for mixing with Europe's low-grade ores. Highest production was 1,340,408 metric tons of concentrates in 1939.

Sierra Leone.—Exports of high-grade ore from the Marampa iron mines in Sierra Leone to Great Britain approached a million tons in 1948,[32] and expansion plans were being given serious consideration. The undeveloped deposits in the Tonkolili area have proved reserves of [33] 100 million tons containing 55–60 percent iron with low sulfur and silica. Both the Marampa and Tonkolili deposits are owned by the Sierra Leone Development Co., Ltd.

Southern Rhodesia.—Reserves of domestic iron ore have been proved adequate for the needs of the furnaces built in 1948 for the Rhodesian Iron and Steel Commission.[34]

Sweden.—The Geological Inspection Department of Sweden stated in a report [35] to the Government, that as known iron-ore fields are capable of providing all the ore that can be transported or marketed in present circumstances, it was unreasonable to expect the Government to bear the expense of further exploration. Thus, Sweden presents the unusual case of a restricted rather than expanded search for mineral resources.

Turkey.—The Divrigi iron mine, which supplies the Karabuk Iron & Steel Works in Turkey, will increase output to enable the two blast furnaces to operate at capacity. It is planned to divert coke from other industries if necessary to obtain additional pig iron.[36]

Union of South Africa.—Undeveloped reserves in the Union have been estimated [37] at over 6 billion tons containing over 40 percent iron. Of these reserves 120 million tons are high-grade hematite containing over 60 percent iron.

United Kingdom.—Recent reviews describe British beneficiation and blending practices which allow use of domestic low-grade ores.[38] [39]

Venezuela.—Publication of the results of explorations by American firms in Venezuela revealed the importance that country will assume in the future iron-ore supply pattern of the United States.[40] The concessions of the U. S. Steel Corp. include a number of known deposits distributed over a wide area, but one deposit overshadowed all others and is the one selected for initial exploitation. This deposit, now known as Cerro Bolivar, contains over half a billion tons of high-grade ore. Cerro Bolivar is a small mountain 50 miles due south of Ciudad Bolivar. It rises 2,000 feet above the surrounding savanna country and is about 11 miles long. The area covered by drilling was 18,000 feet by 1,200 feet, with holes usually bottomed in quartzite at an average ore depth of 148 feet. Samples of ore contained 10 percent moisture, indicating an average natural iron content of 56.7 percent.

The biggest problem remaining to be overcome is transportation. A choice must be made between utilizing the Orinoco River and building a railroad across country 274 miles to a tidewater terminal near Barcelona. If the river is decided upon, a railway must be built between Cerro Bolivar and the confluence of the Orinoco and Caroni Rivers, a distance of 91 miles; from there a channel must be dredged deep enough for the largest oceangoing ore carriers or barges for transferring ore to ocean vessels at tidewater. Eventually, the corporation expects to ship over 13 million tons annually. Distance to United States consuming centers are of particular interest. From Cerro Bolivar to Orinoco River port, 91 miles; thence to tidewater, 170 miles; mouth of the Macareo River (central Orinoco delta branch)

to Baltimore, 2,280 miles; to Mobile, 2,460 miles; Mobile to Birmingham, 276 miles (rail) and 280 miles (water); Barcelona to Mobile or Baltimore, 2,190 miles.

The Bethlehem Steel Corp. has developed the El Pao deposit to the point of production. Shipments had been expected in 1949; but difficulties at the ocean terminal, Puerto Hierro, had not been cleared by year's end. Shipments by way of Bethlehem's facilities are expected ultimately to reach 3 million tons annually. These facilities were described.[41]

Iron and Steel

By Norwood B. Melcher

GENERAL SUMMARY

THE domestic steel industry of 1949 suffered severe production set-backs resulting from numerous work stoppages at coal mines and one of the most costly steel strikes in the Nation's history. In the second and third quarters, production also declined from a general business recession attributed in large part to cautious buying policies by the major steel-consuming industries. This recession, which affected many industries other than steel, was due only in part to lower consumer purchasing; consequently a substantial portion of sales was made from inventories, whereas in 1948 production went both to consumers and to building up inventories. As a result of these factors, the rate of steel production declined from 94.1 percent of capacity in 1948 to 81.1 percent in 1949. The production of steel ingots and castings declined 12 percent, and pig iron dropped 11 percent during the year.

The steel strike of 1949 was called at 12:01 a. m. October 1, and steel production immediately dropped to the lowest operating rate (percentage of capacity) in history and the lowest tonnage output since July 1932. Operations were limited to production of a few relatively small independent companies and averaged only 11.2 percent of capacity. On October 31 the Bethlehem Steel Co. signed agreements with the United States Workers providing for a company-financed pension program and company-employee social security insurance benefits effective January 1, 1950; other large companies signed similar agreements on November 8, followed by a settlement with the United States Steel Corp. November 11. By the time furnaces were back in full production, virtually 6 weeks had elapsed, and 10,000,000 tons of steel ingots were lost from the 1949 output. Steel production recovered quickly, however; a major backlog of steel orders had accumulated during the strike, and it was evident that steel would be produced at a high rate in the early months of 1950.

Of the major steel-consuming industries, the automotive industry was an outstanding exception to a lower steel use pattern in 1949 as compared with the previous year. That industry established all-time records in production during 1949 in producing 5,114,269 passenger cars and 1,123,792 trucks. In this record production the industry received 11 million tons of steel products or 19 percent of the shipments to all consuming industries. The high demand for automobiles continued throughout the year in spite of the general slackening in consumer demand for most products. Dealers were still unable to accumulate inventories of most models, even at the close of 1949, and prospects forecast even greater production and consequent higher steel requirements in 1950.

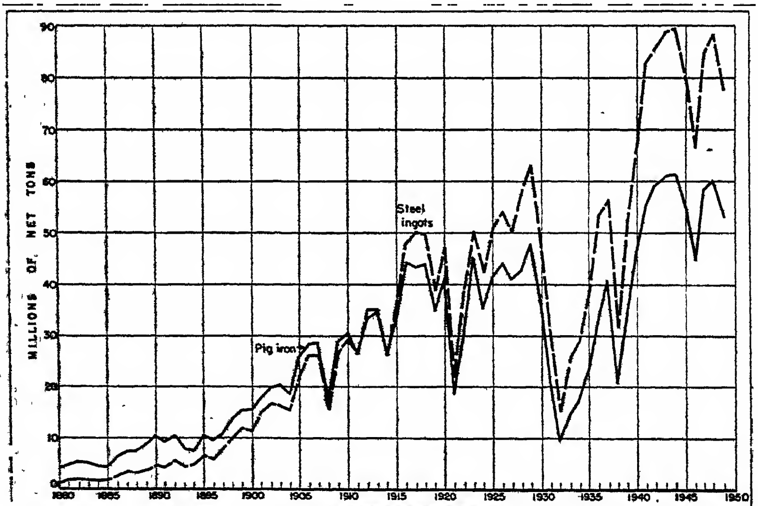

FIGURE 1.—Trends in production of pig iron and steel ingots in the United States, 1880–1949.

According to Steel magazine, steel-plant expenditures totaled 627 million dollars in 1949 compared with 583 million dollars in 1948 and 496 million in 1947. The construction industry (including contractors' products, such as plumbing and heating equipment) in 1949 obtained a slightly larger proportion of total steel than in 1948, although the tonnage received was 2 percent less. Construction of

dwelling units was high in 1949, with 1,023,000 units started during the year. Total new construction during the year was valued at 19.3 billion dollars compared with 17.7 billion in 1948. Of this total, 14.1 billion was private construction. Residential accounted for one-half of the total private building. The container industry required less steel in 1949, but the market for metal containers continued strong throughout the year. New products were being packaged in cans owing partly to the transportation advantages of metal containers. Electrolytic tin-plate production continued to increase in 1949 and is reported to have exceeded the production of hot-dipped tin and terneplate for the first time.[1] The withdrawal of most Government restrictions on the use of tin plate December 1, 1949, may result in a larger use of hot-dipped plate in 1950.

Railroads received 6 percent of the steel products in 1949 compared with 8 percent in 1948, and a still lower level of steel purchasing by this industry in 1950 was anticipated. An increasing trend in the use of truck transportation for steel products may result in lower requirements for railroad cars for this service. Freight-car loadings in 1949 were reduced substantially in the second quarter and reached a low of 2,399,000 in October. Shipbuilding requirements increased slightly over 1948 but still used only slightly more than 1 percent of total steel products in 1949. Steel products for export also increased slightly from 1948, with pipes and tubes showing the largest increases, according to the U. S. Department of Commerce. In the semimanufactures, plate and sheets were the largest tonnage items and those that showed the greatest increase over the previous year.

The steel industry continued to operate on a 40-hour-a-week basis during 1949, although the average weekly hours per worker was only 37.9, resulting from a low average during the strike months of October and November. Average weekly wages decreased during the year from $66.24 in January to $64.56 in December. Total employment declined from 550,000 in January to 505,000 at the end of the year. The composite price of finished steel as published by Iron Age dropped for five consecutive months from 3.720 cents to 3.705 cents in June and continued at this rate until December, when price increases resulted in an all-time high of 3.756 cents.

PRODUCTION AND SHIPMENTS OF PIG IRON

Domestic production of pig iron, exclusive of ferro-alloys, decreased 11 percent from 1948 and was the lowest since 1946. Pennsylvania and Ohio, the first- and second-largest States in pig-iron production, produced proportionately less pig iron than in any previous year. Pennsylvania produced 28 percent of the total in 1949, and Ohio produced 20 percent as compared to 30 and 21 percent, respectively, in 1948, proportions that had prevailed for four consecutive years. Of the pig iron manufactured in 1949, 2,260,000 tons valued at approximately $95,000,000 were made from 4,447,322 tons of foreign iron and manganiferous ores from Algeria, Brazil, Canada, Chile, Cuba, India, Mexico, Sweden, and Union of South Africa. Domestic ore (78,334,130 tons) and sinter (14,267,073 tons)

[1] Steel, vol. 126, No. 1, Jan. 2, 1950, p. 105.

and 7,865,225 tons of miscellaneous materials were reported used in manufacturing 51,063,142 tons of pig iron. In addition to these raw materials, 1,491,501 tons of home scrap and 171,223 tons of flue dust were consumed in making pig iron in 1949.

Pig iron produced and shipped in the United States, 1948–49, by States

State	Produced		Shipped from furnaces			
	1948 (net tons)	1949 (net tons)	1948		1949	
			Net tons	Value	Net tons	Value
Alabama	4,013,771	3,662,801	3,980,677	$145,358,582	3,664,801	$131,162,133

Total	60,973,140	53,323,142	60,051,350	2,232,121,837	52,919,019	2,225,294,357

[1] Data that may not be shown separately are combined as "Undistributed."

Shipments of pig iron decreased 12 percent in quantity but less than 1 percent in value from 1948. The values given in the accompanying table represent the approximate amounts received for the pig iron, f. o. b. furnaces, and do not include freight costs, selling commissions, and other items normally included in market prices for pig iron as published by trade journals.

Pig iron shipped from blast furnaces in the United States, 1948–49, by grades

Grade	1948			1949		
	Net tons	Value		Net tons	Value	
		Total	Average		Total	Average
Foundry	2,759,989	$110,686,035	$40.10	2,329,408	$91,817,177	$39.42
Basic	47,067,134	1,742,756,234	37.03	41,434,250	1,739,650,516	41.99
Bessemer	7,105,015	268,311,270	37.76	6,459,006	280,109,520	43.37
Low-phosphorus	389,119	17,250,121	44.33	221,847	10,190,651	45.94
Malleable	2,598,494	87,492,509	33.77	2,332,940	97,392,445	41.75
All other (not ferro-alloys)	139,599	5,625,668	40.30	141,568	6,134,048	43.33
Total	60,051,350	2,232,121,837	37.17	52,919,019	2,225,294,357	42.05

Metalliferous Materials Used.—The production of pig iron in 1949 required 97,048,525 short tons of iron ore, sinter, and manganiferous iron ore, 2,981,178 tons of mill cinder and roll scale, 3,353,665 tons of open-hearth and Bessemer slags, 1,502,504 tons of purchased scrap, and

27,655 tons of other miscellaneous materials—an average of 1.968 tons of metalliferous materials (exclusive of home scrap and flue dust) per ton of pig iron made.

Alabama furnaces used red hematite from the Birmingham district and brown ores from Alabama and Georgia, as well as hematite from Missouri and the Lake Superior region. Pyrites cinder was shipped from Virginia and sintered with Alabama red ores, and cinder and byproduct ore were obtained from Tennessee. Foreign iron ore from Brazil and Sweden, foreign manganese-bearing ores from Africa, Chile, India, and Mexico, and a small quantity of domestic material were also used.

Blast furnaces at Fontana, Calif., used iron ore from the Eagle Mountain and Vulcan mines in California and from the Excelsior mine in Utah. The small quantity of manganese ore used originated in Mexico.

The iron ore consumed in furnaces at Pueblo, Colo., originated from the Duncan and Blowout mines, Iron County, Utah, and the Sunrise mine, Platte County, Wyo. Manganiferous iron ore from the Boston Hill mine, Grant County, N. Mex., was also used.

The blast furnaces at Sparrows Point, Md., used various domestic iron ores and foreign iron ore from Africa, Brazil, Chile, Cuba, and Sweden; the foreign manganiferous ores used there were imported from Algeria and the Union of South Africa. The bulk of the manganiferous material used was mined domestically on the Cuyuna range in Minnesota.

Blast furnaces (including ferro-alloy blast furnaces) in the United States, 1948–49

Blast furnaces in Illinois, Kentucky, Michigan, and Minnesota used Lake Superior iron ore and manganiferous ore exclusively. Indiana furnaces used all Lake Superior iron ore and a small quantity of manganese ore from the Union of South Africa. West Virginia furnaces used Lake Superior iron ore from mines in Canada and the United States.

Iron ore and other metallic materials consumed and pig iron produced, 1948–49, by States, in net tons

[1] Excludes recycled materials.

The Everett, Mass., blast furnace used iron ores from Algeria, Newfoundland, and Sweden, as well as from the Lake Superior region. In New York, the blast furnaces in the Buffalo district used magnetite from the Mineville district in New York and hematite from Canadian and domestic mines in the Lake Superior region, as well as manganiferous ores from Minnesota. The Troy furnace consumed magnetite from the Chateaugay mine at Lyon Mountain, N. Y., and manganese ore from South Africa.

Ohio blast furnaces consumed magnetite sinter from New York, hematite from Canada, and iron and manganiferous ores from mines in the Lake Superior district.

Western Pennsylvania furnaces obtained the bulk of their iron ore from the Lake Superior district. Furnaces in the eastern part of the State used some Lake Superior ore and some magnetite ore from New Jersey, New York, and Pennsylvania. Eastern Pennsylvania furnaces also used iron ore from Africa and Sweden, while the western furnaces used foreign ores from Canada only; small quantities of pyrites cinder (both domestic and foreign) were used at eastern Pennsylvania furnaces.

Texas blast furnaces used brown iron ore from eastern Texas, as well as a considerable tonnage from Mexico; manganese ore from Mexico was also used.

Utah furnaces used semialtered magnetite from the Iron Mountain mine in Iron County, Utah, and manganiferous ores from Nevada and Utah.

Foreign iron and manganiferous iron ore consumed in the manufacture of pig iron in the United States, 1948–49, by sources of ore, in net tons

PRODUCTION OF STEEL

Steel production decreased 12 percent in 1949 from 1948, but steel capacity continued to increase. Capacity at the end of 1949, as published by the American Iron and Steel Institute, totaled 96,120,930 short tons; this figure, however, had been carried throughout 1949 and in January 1950 was revised to include new additions to capacity and totaled 99,400,000 tons. Of the total tonnage of steel ingots and castings produced in the United States in 1949, 90 percent was made in open-hearth furnaces compared with 89 percent in 1948; 5 percent was made in Bessemer converters, as during the previous year, and 5 percent was made in electric furnaces compared with 6 percent in 1948.

In 1949, 38.7 percent of the domestic steel output was made by furnaces in the Pittsburgh-Youngstown district, 22.0 percent in the Chicago district, 19.8 percent in the Eastern district, 9.0 percent in the Cleveland-Detroit district, 5.5 in the Western district, and 5.0 percent

in the Southern district, compared with 40.1, 21.7, 19.5, 8.5, 5.3, and 4.9 percent, respectively, in 1948.

The data concerning steel production used by the Bureau of Mines are furnished by the American Iron and Steel Institute. The output from steel foundries that do not produce steel ingots is not included in the production data.

Steel capacity, production, and percent of operations, 1945–49, in net tons [1]

Alloy Steel.—The steel output for 1949 includes 5,897,569 net tons of alloy steel ingots and castings, the lowest production of alloy steel since 1940. This production represents less than 8 percent of the total steel compared with 10 percent in 1948. The alloy-steel data include steels

Steel electrically manufactured in the United States, 1945–49, in net tons [1]

[American Iron and Steel Institute]

Year	Ingots	Castings	Total	Year	Ingots	Castings	Total
1945	3,381,678	75,026	3,456,704	1948	4,973,611	83,530	[2] 5,057,141
1946	2,479,064	83,960	[2] 2,563,024	1949	3,687,077	95,640	[2] 3,782,717
1947	3,680,500	107,217	3,787,717				

[1] Includes only that portion of steel for castings produced in foundries operated by companies manufacturing steel ingots.
[2] Includes a very small quantity of crucible steel.

in which the minimum of the range specified, in one or more of the elements named, exceeds the following percentages: Manganese, 1.65 percent; silicon, 0.60 percent; copper, 0.60 percent, or aluminum, boron, chromium, cobalt, columbium, molybdenum, nickel, titanium, tungsten, vanadium, zirconium, and other alloying elements, any added percent. The output of alloy steels in 1949 decreased 30 percent from 1948, whereas total steel decreased only 12 percent. Of the alloy steel produced in 1949, 71 percent was made in basic open-hearth furnaces, 2 percent in acid open-hearths, and 27 percent in electric furnaces; none was produced in Bessemer converters.

Electric furnaces produced proportionately more alloy steel in 1949 than in 1948; 42 percent of the steel made in electric furnaces was alloy compared with 41 percent in the previous year. Typically, steels with high alloy content are made in electric furnaces and steels with lower content by the open-hearth process.

Metalliferous Materials Used.—During 1949 steel furnaces used 3,152,797 net tons of domestic iron ore and 1,107,625 tons of foreign ore; the latter originated in Africa, Brazil, Canada, Cuba, and Sweden. Also used were 1,051,746 tons of sinter made from both foreign and domestic ores. Scrap and pig iron used in steel furnaces in 1949 totaled 86,930,717 net tons; of this, 54 percent was pig iron, 26 percent home scrap, and 20 percent purchased scrap. Both charge ore and feed ore are employed in the basic open-hearth process. Charge ore is used to add oxygen to the charge before it is melted. This ore should be low in combined and uncombined moisture, silica, and fines. Ore with a high silica content requires large additions of limestone

and consequently produces large volumes of slag, which reduces furnace efficiency. Iron-ore sinter has been found to be a good charge ore in open-hearth practice.

Feed ore, which is added to the heat during the working period, should be hard, dense, coarse, and low in moisture. Although moderately high silica ore can be used as feed, it is undesirable as a charge ore because of the large quantity of slag resulting. Lump ore, which is preferred as a feed ore, is high-priced, and the supply is limited. The Vermilion range in Minnesota and the Adirondack district in New York are the large source of this grade in the United States. Recently, large tonnages of high-grade lump ore have been obtained from Brazil.

[1] Preliminary.

CONSUMPTION OF PIG IRON

Consumption of pig iron in 1949 decreased 11 percent from 1948. Pig iron, a product of the blast furnace, is a semiraw material; except for a small quantity used in direct castings, it moves to steel- or iron-melting furnaces for refining, alone or mixed with other ingredients. In 1949, 87 percent of the pig iron went to steel-making furnaces (open-hearth, Bessemer, and electric) to be processed into steel. Direct castings took 4 percent; and the remaining 9 percent was consumed in iron-making furnaces, of which the cupola is the most important. Gray-iron foundries used 10 percent less pig iron in 1949 than in 1948, but this was 9 percent of the total pig iron in 1949 as in 1948.

[1] In 1947 some pig iron consumed in California, Illinois, Kentucky, Maryland, New Jersey, Ohio, and Pennsylvania—not separable—is included with "Undistributed."

Plants using pig iron in 1949 were located in all 48 States and in the District of Columbia, but consumption is concentrated largely in the steel-making centers of the North Central, Middle Atlantic, and the Southeastern States. These areas used 95 percent of the pig iron in 1949; Pennsylvania (the leading consumer) took 28 percent of the total and Ohio (the second largest consumer) 19 percent.

PRICES

The average value of all grades of pig iron given in the accompanying table is compiled from producers' reports to the Bureau of Mines. The figures represent value f. o. b. blast furnaces and do not include the value of ferro-alloys. The general average value for all grades of pig iron at furnaces was $42.05 a net ton in 1949 compared with $37.17 in 1948.

Average value per net ton of pig iron at blast furnaces in the United States, 1945–49, by States

State	1945	1946	1947	1948	1949
Alabama	$18.39	$21.15	$28.12	$36.52	$35.79
California, Colorado, and Utah	19.49	21.25	30.50	40.93	42.92
Illinois	22.98	25.17	30.97	35.72	41.69
Indiana	23.11	25.46	30.57	37.86	41.26

FOREIGN TRADE[2]

The ability of domestic furnaces to more nearly meet demands for pig iron in 1949 resulted in sharp decreases in imports in the United States during the year. Particularly noticeable were the lower receipts from France, Germany, Netherlands, and Norway.

Pig iron imported for consumption in the United States, by countries, 1945–49, in net tons

Country	1945	1946	1947	1948	1949
North America:					
Canada	21,433	1,287	1,747	5,729	12,270

Value	$440,283	$492,519	$1,738,812	[1] $11,977,534	$4,591,779

[1] Revised figure.

Relaxation of export controls in 1949 resulted in large increases of pig-iron exports to Canada, United Kingdom, and Korea during the year. Exports increased from 7,032 net tons ($217,237) in 1948 to 81,309 tons ($3,353,602) in 1949. Of the 1949 total, 46,990 tons went to United Kingdom, 19,163 to Canada, 8,346 to Korea, 2,280 to Mexico, 1,690 to Greece, and the remaining 2,840 tons, in small lots, principally to Central and South America.

[2] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Imports and exports of iron and steel products are given in detail in the following tables. Imports of semimanufactures—steel ingots, blooms and slabs, steel bars and plates, and tin plate—increased considerably. Of the manufactures, structural showed the largest tonnage increase during the year. Exports of semimanufactures and manufactures increased slightly.

Iron and steel imported for consumption in the United States, 1947–49,[1] by products

[1] Revised figure.

WORLD PRODUCTION

World production of steel in 1949 increased slightly over 1948 despite the 12-percent drop in United States output. Notable increases occurred in the U. S. S. R., the world's second largest producer, and Germany, which attained its largest postwar production although the rate was less than in any war year, due in part to limitations imposed by the Allied Control Authority. Japanese production increased in 1949 but was restricted by raw-material shortages.

Australia.—The Broken Hill Pty. Co., Ltd. (B. H. P.), was permitted by the Capital Issues Advisory Committee to increase its capital £6,942,450. The new capital is to be used for expansion of the B. H. P. and its principal subsidiary, Australian Iron & Steel Ltd., including mechanization of coal mines, building of ore-carrying vessels, development of iron-ore property at Cockatoo Island, and completion of a new rolling mill, coke ovens, hot and cold strip mill, and tin-plate plant at Port Kembla.[3] B. H. P. and Australian Iron and Steel Ltd. produce all of the iron and steel in Australia.

Chile.—An agreement was signed early in 1949 between the Bethlehem Chile Iron Mines, a subsidiary of Bethlehem Steel Co., and Compania de Acero del Pacifico; the agreement is reported to include the development of the El Romeral iron-ore deposits in La Serena Department and is to begin within 3 years.[4]

Colombia.—A report by Koppers Co., Inc., for the Institute de Fomento Industrial on the proposed steel plant at Belencito near Sogamoso, Department of Boyaca, Colombia, was completed during 1949; the plant is designed to produce 193,530 tons of iron and steel products during the first year (1953) and increase to 216,300 tons annually at the end of 1957; the ore for this operation will come from Paz de Rio, where reserves are stated to be 20,400,000 tons of iron ore

and 1,500,000 tons of manganiferous ore. The iron ore is said to contain 47 percent Fe and 16 percent SiO_2, some AO_2O_3, with a 12-percent ignition loss. Coal and other raw materials are said to be available in areas easily accessible to the plant site.[5]

Germany: Soviet Zone.—In the Soviet Zone of Germany, rolled-steel production in 1948 has been given as 230,000 metric tons, of which 80,000 tons came from the Hüttenwerk Thale and 130,000 tons from Maximilianhütte; these two operations were transferred to Russian ownership in 1945 and continued in operation, while the remaining iron and steel works at Riesa, Gröditz, Döhlen, Brandenburg, and Henningsdorf were largely dismantled. In 1947 authorization was granted by the Soviet Military Government for reconstruction of the

[1] Fiscal year ended June 30 of year stated.
[2] Estimate.
[3] September to December, inclusive.
[4] Data not available.
[5] Data from American Iron and Steel Institute. Excludes production of castings by companies that do not produce steel ingots.

Riesa and Henningsdorf works and the return of Maximilianhütte to the Government of Thuringia. Reconstruction, however, has been very slow, and it is doubtful whether production in the Soviet Zone exceeded 500,000 tons in 1949.[6]

Israel.—A rolling mill for the production of reinforcing bars and light structural shapes was purchased in France and delivered to Haifa in 1949. The capacity of the mill is given as 40,000 tons annually.[7] Plans were made public later in the year for a plant to be constructed at Tel Aviv for production of steel as well as fabrication.[8]

Norway.—Plans were furthered in 1949 for construction of a proposed steel plant in northern Norway, mentioned in Minerals Yearbook, 1947.[9] The capacity goal has been given as 500,000 tons of finished products per year. Iron ore will probably come from the large deposits at Dunderland.[10]

Iron and Steel Scrap

By James E. Larkin

GENERAL SUMMARY

WIDE fluctuations in price and consumption of ferrous scrap were experienced by the scrap industry during 1949. Steel mills operated at more than 100 percent of capacity during the first quarter of 1949 and used more scrap than they were able to obtain, the difference in their metal charges being made up by drawing from their inventories. Heavy collections of scrap were made during the mild winter months, which resulted in less scrap being available in the second quarter. Thereafter, steel mills continued to purchase less scrap, and prices dropped precipitously to the lowest level in 5 years. Surplus scrap, which had been made available by the Government during 1948, was about exhausted; hence consumers could not rely upon this source of scrap to replenish their stocks. The higher prices paid during 1948 had enabled small dealers and collectors to operate and had brought out a large enough supply to permit a new record consumption of purchased scrap in that year and a 60-percent increase in consumers' stocks at the end of 1948. However, the drop in scrap prices during 1949 to nearly the Office of Price Administration wartime level caused some of these dealers and collectors to discontinue operations, thus decreasing this source of supply.

A 12-percent drop during 1949 from 1948 in the output of steel ingots and castings was accompanied by a 16-percent decrease in the use of scrap and a 14-percent decrease in the use of all ferrous materials. The demand for steel remained high during the first quarter of the year; however, production was curtailed during the balance of the year owing to lack of demand resulting from a general business recession in the second and third quarters, strikes in associated industries, and a costly steel strike beginning October 1 and lasting until November 11.

Stocks of purchased scrap held by consumers decreased each month after January and continued to decrease until the end of September, when they reached the 1949 low of 3,292,000 short tons. The steel strike curtailed the consumption of purchased scrap; however, consumers were obliged to accept some commitments for scrap to be delivered during October and November, resulting in an increase in inventories up to the end of the year. Although stocks had increased at the end of the year, they were still 16 percent lower than at the beginning of the year and were equivalent to a 59-day supply at the 1949 average daily consumption rate of 68,964 short tons.

As a result of the steel strike, the estimated use of ferrous scrap and pig iron in steel-making furnaces during October (1,080,000 net tons) dropped to a level lower than in any month since collection of monthly statistics by the Bureau of Mines was begun in July 1941. In contrast to this low level in October, the Bureau of Mines estimated that a record total of 9,418,000 net tons of ferrous materials was used in

steel-making furnaces during March in producing an all-time high of 8,401,796 net tons of steel ingots and castings. This record consumption was achieved by melting a new high of 4,991,000 net tons of pig iron; purchased scrap was the highest (2,116,000 net tons) since March 1948 and home scrap (2,311,000 net tons) the highest since March 1945.

Salient statistics of ferrous scrap and pig iron in the United States, 1948–49

	1948 (short tons)	1949 (short tons)	Percent of change from 1948
Stocks, December 31: Ferrous scrap and pig iron at consumers' plants:			
Home scrap	1,598,673	1,564,054	−2

Basic	$41.62	$46.00	+11
No. 2 Foundry	$42.12	$46.50	+10

[1] Includes open-hearth, Bessemer, and electric furnaces.
[2] Includes cupola, air, Brackelsberg, puddling, crucible, and blast furnaces; also direct castings.
[3] Includes rerolling, reforging, copper precipitation, nonferrous, and chemical uses.
[4] Revised figure.
[5] Iron Age.

The Scrap Drive Committee appointed during November 1948 by the Secretary of Commerce to assist the Office of Industry Cooperation in a Nation-wide industrial iron- and steel-scrap drive was asked in April 1949 to terminate the campaign as of May 15, because of

improvement in the scrap supply situation. The Secretary of Commerce stated, in connection with termination of this drive:

> Although the quantities of scrap available at the moment are adequate to take care of the country's needs for peacetime operations, it should be made plain that there is no excessive quantity of scrap in the United States. If steel production is to continue at the present high rate and if consumer demands for steel products are to be met, a constant flow of heavy scrap to the steel mills and foundries must be maintained.

He stated further that:

> In commenting on the report of the scrap mission which recently returned from Japan, we do not have the amount of scrap needed in case of an emergency, and the stockpiling of high-grade steel scrap is, in my opinion, desirable.

A four-man mission arrived in Japan in January 1949, to survey the availability of heavy iron and steel scrap in that country. The mission, sponsored by the United States Department of Commerce and the Army, surveyed the scrap and steel industries of Japan so that they could recommend how much scrap the Japanese economy could spare for shipment to the United States. The mission reported that supplies in Japan would amount to more than 5,512,000 short tons.[1] Shipments from that country to the United States have expanded greatly since 1947.

Purchased-scrap stocks as of December 31, 1948, were 4,859,463 short tons and as of January 31, 1949, 4,545,000 short tons. These were the highest stocks held by consumers at any time since the Bureau of Mines has published data on consumers' inventories. These high stocks were evidently a direct result of the scrap drive instigated by the United States Department of Commerce and in the increase from foreign countries.

During April there was a tendency in industry and Government circles toward the stockpiling of iron and steel scrap; however, the Subcommittee on Scrap of the Iron and Steel Industry Advisory Committee of the Munitions Board did not recommend that scrap be stockpiled.

CONSUMPTION

Although there was an over-all reduction in the use of scrap and pig iron in 1949, there was still a noticeably large use of scrap as compared with pig iron in the New England, Pacific Coast, and Southwestern districts. These districts together, as in 1948, used 7 percent of the total scrap consumed in the United States but only 2 percent of the pig iron. The average ratio of scrap to pig iron in these three districts was 3.1:1, whereas for the United States at large it was 1.0:1.

Open-hearth furnaces were still the largest consumers of ferrous scrap and pig iron; however, there was a decrease from 1948 of 5,100,693 tons of scrap and 5,484,828 tons of pig iron used in 1949. Open-hearth consumption accounted for 65 percent of the total scrap in 1949 and 63 percent in 1948; 71 percent of the home scrap in 1949 and 68 percent in 1948; and 59 percent of the purchased scrap in 1949 and 57 percent in 1948. Pig-iron consumption in open hearths

[1] Metal Bulletin (London), No. 3391, May 13, 1949, p. 16.

accounted for 78 percent of the total pig iron consumed in 1949 and 79 percent in 1948.

Cupola-furnace consumption in 1949 was as follows: Home scrap, 15 percent of the total, compared with 16 percent in 1948; purchased scrap, 18 percent, compared with 19 percent in 1948; pig iron, 9 percent in 1949, 1948, and 1947, compared with 10 percent in 1946.

Bessemer converters consumed 9 percent of the pig iron during 1949 compared with 8 percent for the 3 previous years and 0.4 percent of the scrap, the same as in 1948.

Electric furnaces consumed 9 percent of the total scrap, or 1 percent less than in 1948, and 0.2 percent of the pig iron, unchanged from 1947–48.

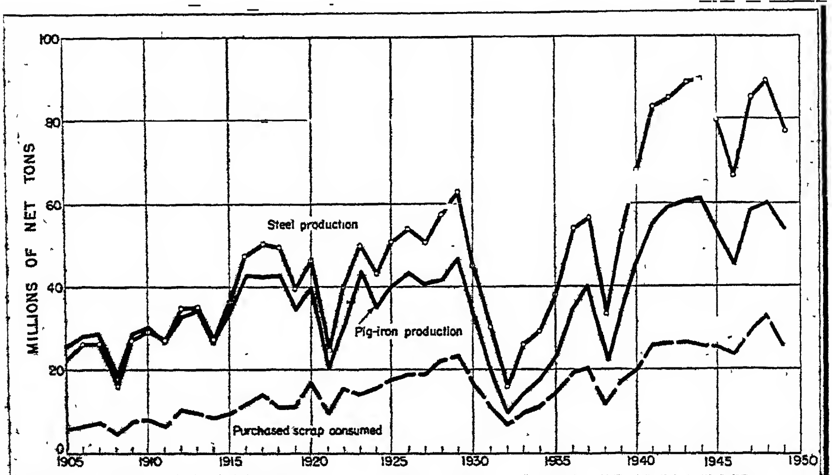

FIGURE 1.—Consumption of purchased scrap and output of pig iron and steel in the United States, 1905–49. Figures on consumption of purchased scrap for 1905–32 are from State of Minnesota vs. Oliver Iron Mining Co., et al., Exhibits, vol. 5, 1935, p. 328; those for 1933–34 are estimated by authors; and those for 1935–49 are based on Bureau of Mines reports. Data on steel output from the American Iron and Steel Institute.

CONSUMPTION BY DISTRICTS AND STATES

During 1949 iron and steel scrap and pig iron were used in all 48 States and the District of Columbia; none was used in Alaska. As in 1948, the largest consuming districts were North Central, Middle Atlantic, and Southeastern. All districts decreased from 1948 in

total scrap and pig iron. The States having the largest consumption of scrap, with the percentage consumed, were: Pennsylvania 23, Ohio 17, Illinois 10, Indiana 10, Michigan-Wisconsin 9, and New York 5.

CONSUMPTION BY TYPE OF FURNACE

Open-Hearth Furnaces.—Ferrous scrap and pig-iron consumption in open-hearth furnaces in 1949 totaled 77,304,960 short tons, a decrease of 12 percent from 1948. Regardless of the decrease from 1948, a record year, the use of ferrous scrap and pig iron consumed in open-hearth furnaces in 1949 exceeded the quantity in any other peacetime year for which the Bureau of Mines has collected these data. The use of home scrap decreased 7 percent, purchased scrap 20 percent, total scrap 13 percent, and pig iron 12 percent. The open-hearth furnace melt in 1949 consisted of 46 percent scrap and 54 percent pig iron, unchanged from 1948. Of the total scrap consumed, 42 percent was purchased compared with 46 percent in 1948 and 45 percent in 1947.

Pennsylvania again led in the use of scrap in the open-hearth in 1949, followed in order by Ohio, Indiana, and Illinois; this rank has remained unchanged since 1936. In 1935, the first year data were compiled on iron and steel scrap, Ohio consumed the largest quantity, followed by Pennsylvania, Indiana, and Illinois.

Bessemer Converters.—The 4,821,574 short tons of ferrous raw materials used in Bessemer converters in 1949 represent a 4-percent decrease from the 1948 use of these materials. The proportion of scrap in the metal charges was 1: 23, and of the scrap used 82 percent was home scrap.

Following the usual pattern, Pennsylvania was the principal consumer of converter scrap in 1949.

Electric Steel Furnaces.—The melt of ferrous scrap and pig iron used in electric furnaces in 1949 totaled 4,804,183 short tons, a 30-percent decrease from the 6,837,817 tons used in 1948. Decreases in the use of scrap occurred in all districts; pig iron decreased in all except the Rocky Mountain, Southeastern, and Southwestern. This over-all decrease in electric furnace consumption resulted from strikes in the steel and allied industries.

Cupolas.—Preliminary figures released by the Bureau of the Census, United States Department of Commerce, indicate that shipments of gray-iron castings in 1949 decreased approximately 18 percent from 1948. Accordingly, requirements for scrap and pig-iron cupola consumption decreased in 1949. Cupola furnaces used 13,521,458 short tons of scrap and pig iron, a 19-percent decrease from the 16,747,964 tons used in 1948. The use of home scrap decreased 18 percent, purchased scrap 28 percent, and total scrap 24 percent; pig iron decreased 10 percent.

Charges to cupolas consisted of 32 percent home scrap, 33 percent purchased scrap, and 35 percent pig iron compared with 32, 37, and 31 percent, respectively, in 1948.

As in 1948, Michigan continued to be the largest consumer of cupola scrap, followed in order by Ohio, Illinois, Pennsylvania, Alabama, Indiana, Wisconsin, New York, and New Jersey.

Air Furnaces.—Scrap and pig iron consumed in air furnaces (including two Brackelsberg) in 1949 amounted to 1,174,239 short tons, a decrease of 33 percent from the 1,748,978 tons melted in these furnaces in 1948. The use of home scrap decreased 33 percent and of purchased scrap 38 percent; pig iron decreased 26 percent.

Ohio led in the use of scrap in air furnaces, followed in order by Illinois, Pennsylvania, Indiana, Wisconsin, Michigan, and New York.

[1] Includes 2 Brackelsberg furnaces, 1 each in Indiana and Ohio.

Crucible and Puddling Furnaces.—Crucible furnaces used 1,211 short tons of scrap and 1,052 tons of pig iron in 1949 compared with 1,329 and 1,013 tons, respectively, in 1948. Puddling furnaces used 6,674 tons of scrap and pig iron. Of the total puddling-furnace melt in 1949, 2,794 tons were scrap compared with 4,802 tons during the previous year. All of the scrap and pig iron consumed in puddling furnaces was in Pennsylvania.

Blast Furnaces.—Materials other than scrap constitute by far the largest proportion of the blast-furnace charge and in 1949 consisted of 97,048,525 short tons of iron ore, sinter, and manganiferous ore; 2,981,178 tons of mill cinder and roll scale; 3,353,665 tons of open-hearth and Bessemer slag; and 27,655 tons of miscellaneous materials.

Total consumption of scrap in 1949 by 72 plants operating blast furnaces was 3,006,881 short tons, a 3-percent increase over 1948. The scrap charged to blast furnaces was 50 percent home and 50 percent purchased, compared with 49 and 51 percent, respectively, in 1948 and 52 and 48 percent, respectively, in 1947. The proportion of scrap used to pig iron produced was 5.6 percent compared with 4.9 percent in 1948; home scrap 2.8 percent and purchased scrap 2.8 percent in 1949.

USE OF SCRAP IN FERRO-ALLOY PRODUCTION

The producers of ferro-alloys (by other than blast furnaces) in 1949 consumed 295-687 short tons of scrap, a 16-percent decrease from 1948. Of this total, 172 tons were used in the aluminothermic process and the balance in electric furnaces. Scrap used in blast furnaces in the manufacture of ferro-alloys is included in this chapter with blast furnaces. Purchased scrap accounted for 97 percent of the quantity used and home scrap 3 percent; in 1948 the percentages were the same.

Eighteen ferro-alloy plants used ferrous scrap in 1949, the same as in 1948. Of these plants, 17 operated electric furnaces. One of this group employed both the electric and aluminothermic process, and one additional plant used the aluminothermic process only.

MISCELLANEOUS USES

Scrap consumed in 1949 for miscellaneous purposes, such as rerolling, nonferrous metallurgy, and as a chemical agent, remained at slightly less than 2 percent of the total consumption. This percentage has been unchanged for the past 5 years. The quantity so used—945,256 short tons—was a decrease of 24 percent from that used for these purposes in 1948. Of the quantity used, 95 percent was purchased and 5 percent home scrap.

[1] In addition, 53 tons of pig iron were consumed in miscellaneous uses in Montana during 1949.

STOCKS

Complete iron- and steel-scrap stock figures covering 1949 year-end stocks are not available; producers (railroads and manufacturers) were not canvassed. Dealers and automobile wreckers reporting to the Bureau of Mines had 324,387 short tons of material on hand December 31, 1949, compared with 193,108 short tons at the end of 1948, an increase of 131,279 or 68 percent. Shipbreakers reported 97,886 short tons of material on hand December 31, 1949.

Consumers' Stocks.—Consumers' stocks of home and purchased iron and steel scrap on December 31, 1949, totaled 5,640,859 short tons—a decrease of 817,277 short tons or 13 percent from the beginning of the year. Stocks of home scrap (1,564,054 tons) decreased 2 percent and purchased scrap (4,076,805 tons) decreased 16 percent. Stocks of pig iron on December 31, 1949, amounted to 1,657,634 short tons, an increase of 3 percent over the 1,606,160 short tons on hand December 31, 1948.

Consumers' stocks of ferrous scrap and pig iron on hand in the United States on Dec. 31, 1948, and Dec. 31, 1949, by States and districts, in short tons

Suppliers' Stocks.—Stocks of iron and steel scrap in the hands of dealers (317,223 tons) and automobile wreckers (7,164 tons) totaled 324,387 short tons on December 31, 1949, compared with 193,108 tons on December 31, 1948—an increase of 68 percent. Stocks held by shipbreakers amounted to 97,886 short tons on December 31, 1949.

PRICES

The composite price of iron and steel scrap was $41.36 per gross ton during January 1949 but declined to a low of $19.33 per gross ton in July, which was near the level of $19.17 set by the Office of Price Administration during 1942 and 1943. No. 1 Cast scrap at Chicago was selling at $57.25 per gross ton during January 1949, a decrease of $10.75 per ton from January 1948 and $17.05 less than the peak price of $74.30 per gross ton established in August 1948. No. 1 Heavy-Melting steel at Pittsburgh and Chicago was quoted by Iron Age at $41.25 and $40.06, respectively, during January, which was high for the year, but dropped to a low of $20.75 and $19.75 per gross ton during July at Pittsburgh and Chicago, respectively; however, the price showed an upward trend until December when there was a lack of consumer buying and mill rejections. Mills were examining incoming scrap with great care and rejecting supplies deemed not up to the most stringent specifications. This was particularly true of No. 2 bundles.

FOREIGN TRADE [2]

Imports.—Imports of iron and steel scrap, including tin-plate scrap, in 1949 increased nearly two and a half times in quantity (1,140,364 short tons compared with 480,724 tons in 1948) and the same in value ($29,703,389 compared with $12,180,222 in 1948). Of the 1949 imports, 532,850 tons came from Germany, 200,486 tons from the Netherlands, 198,589 tons from Japan, 75,955 tons from the Republic of the Philippines, and the remainder from other countries. There were 45,951 tons of tin-plate scrap imported in 1949 compared with 46,014 tons in 1948, mostly from Canada and Australia.

[2] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

(1) Less than 1 ton.

Exports.—Exports of ferrous scrap from the United States in 1949 were 298,594 short tons valued at $7,342,886, a 41-percent increase in tonnage over 1948 and a 3-percent increase in value. Imports exceeded exports by 841,770 short tons. The tonnage exported amounted to 9 percent of the 5-year prewar average (for 1935–39) of 3,298,326 tons a year, compared with 6 percent during 1948. The 1949 exports included 3,634 tons of tin-plate circles, strips, cobbles, and terneplate clippings and scrap, valued at $395,370. The same materials in 1948 amounted to 3,948 tons valued at $417,128.

Lead

By Richard H. Mote and Edith E. den Hartog

GENERAL SUMMARY

THE TRANSITION in lead supply from insufficiency to abundance accompanied by falling prices highlighted the domestic lead industry in 1949. Noteworthy also was the consumers' cautious buying and general lack of confidence in price stability that resulted in purchases of quantities substantially smaller than actual needs and an 18-percent reduction in consumers' inventories during the year. Some stability was rendered the lead market by the Government through purchase during the year of substantial tonnages of pig lead for the National Stockpile. Contributing to the expanded supply was the high level of imports prevailing in 1949, which resulted in accumulation of nearly 400,000 tons of lead from foreign sources, the largest annual tonnage imported in the peacetime history of the United States.

Although labor strikes continued to exact a toll in reduced output of lead at mines and smelters, the total loss of production was not as great as in 1948. Total mine output advanced 5 percent in 1949, and production of refined lead at primary refineries rose 22 percent to the highest level since 1942. Lead from secondary sources continued for the fourth year to be a greater source of supply than production from domestic mines.

Over-all consumption of primary, antimonial, and secondary lead in the United States in 1949 declined 16 percent from 1948.

Salient statistics of the lead industry in the United States, 1940–44 (average) and 1945–49, in short tons

	1940–44 (average)	1945	1946	1947	1948	1949

[1] Revised figure.

[1] This report deals primarily with the smelting, refining, and consuming phases of the industry. For details of mining operations, see various State chapters of this volume.

DOMESTIC PRODUCTION

Statistics on lead output may be prepared on a mine or smelter and refinery basis. Mine-production data compiled on the basis of lead content in ore and concentrates and adjusted to account for average losses in smelting are a closer measure of output from year to year and are most accurate for showing the geographic distribution of production. Pig-lead output, as reported by smelters and refiners, presents a more precise figure of actual lead recovery but indicates only in a general way the source of crude material treated. Smelter and refinery output generally differs from the mine figure owing to the lag between mine shipments and smelter consumption of ore and concentrates.

MINE PRODUCTION

Domestic mine output of recoverable lead rose 5 percent in 1949 compared with 1948 and was the largest since 1944. This gain reflected the response to the incentive of high market prices during the early part of the year and also fewer interruptions in operation due to labor-management disputes, such as the labor strike that shut down the large lead mines in Southeastern Missouri for 2½ months in 1948 at an estimated loss of 25,000 tons of lead. A downward trend in lead price which began in March and continued through May resulted in some mine closings and reduced workweeks at most large lead-producing properties but failed to offset completely the net gain in output recorded during the early part of 1949. Except for January, production during the first half of the year was at a rate consistently over the 1,123-ton average daily output for the entire year. Production during the latter half of the year, however, fell sharply, and the daily output through November remained below the annual average. The daily production rate in December was 21 percent above the low point of the year, reached in July, but was only 90 percent of the March rate, which was highest for the year.

Production in 11 of the 22 lead-producing States in 1949 exceeded the rates established in 1948, and in some instances record and near-record high outputs were recorded. In Arizona the production was far greater than in any other year in the State's mining history, and not since 1917 have California mines produced as much lead as was recovered in 1949. Colorado lead output reached the highest point since 1927 and in Nevada the 1949 production was larger than for any year since 1936. Similar but less spectacular records were established in the Mid-Continent region, where Oklahoma lead output exceeded that of every year since 1942; Kansas production hit an 8-year high; and Missouri mines closely approached the 1947 output.

Of the total lead produced at United States mines in 1949, 66 percent came from the output of 25 properties. Missouri continued to rank first among the States in the production of lead, and the Southeastern Missouri district continued to be the largest lead-producing area, supplying 31 percent of the total domestic output. As in the past, the St. Joseph Lead Co., produced the bulk of the output from its Bonne Terre, Desloge, Federal (including Doe Run), and Leadwood mine groups in St. Francois County and the Mine La Motte mine in Madison County. Each mine is equipped with a

mill; the five have a combined daily capacity of about 28,800 tons of ore. The St. Louis Smelting & Refining Division, National Lead Co., operated continuously its Madison lead-copper mine and 1,200-ton all-flotation mill at Fredericktown; the output of both lead and copper concentrates showed a large increase over 1948. The Catherine-Fleming mine was operated by the Park City Consolidated Mines Co. from January to March and by the Fredericktown Lead Co. the remainder of the year. In Jefferson County the Fredericktown Lead Co. operated the leased Valle Mine property during January and February and 1 week in May.

Lead production in the Tri-State district gained despite curtailments in rate of ore output and shut-downs caused by falling metal prices. On March 5 the weekly quoted price of lead concentrates at Joplin, Mo., was $290.92 a ton, and in the slightly more than 2 months that followed the quotation dropped without interruption to $148.63 on May 28. About 50 of the mines shut down, and most of the other 76 curtailed production. Output of lead concentrates in June was 34 percent under March production. During July the market price advanced to $183.91 but the monthly production was the lowest of the year, as the mines and mills of the Eagle-Picher Mining & Smelting Co. were shut down by a work stoppage from July 1 to August 7, and other mines shipping to the company's Central mill could not operate during this period. The five leading Tri-State lead-producing companies in 1949, in order of output, were: Eagle-Picher Mining & Smelting Co., Nellie B. Mining Co., Federal Mining & Smelting Co., National Lead Co. St. Louis Smelting & Refining Division, and the W. M. & W. Mining Co. The Tri-State district produced 8 percent of the total domestic lead output in 1949.

Mine production of recoverable lead in the combined Western States dropped 4 percent from 1948. In 1949 lead mines in the region contributed 59 percent of the total domestic production compared with 65 percent in 1948. Idaho was again the largest producer of lead in the Western States and second only to Missouri in the United States. In 1949, 94 percent of the Idaho total lead came from the Coeur d'Alene region. Six properties in the State produced 64 percent of the total lead, 77 percent of which came from zinc-lead ore and old tailings. Lead production in Utah in 1949 declined 5 percent from the 1948 output. Because of a reduced workweek early in May, followed by stoppages late in June at three of the large lead producers and serious curtailment at the fourth in the Park City region, production of lead for the year declined substantially at the properties of the New Park Mining Co., Park Utah Consolidated Mines Co., Silver King Coalition Mines Co., and Pacific Bridge Co. The Calumet mine in the Rush Valley district also produced less lead than in 1948. These losses were compensated in part by increases in lead yield from the United States & Lark group, Chief Consolidated Mining Co. property, Butterfield group, Cardiff mine, and the Hidden Treasure mine, and the return to production of the New Park Mining Co. property on September 15. The United States & Lark property of the United States Smelting, Refining & Mining Co. in the West Mountain (Bingham) district remained first among the State lead producers. Of the State total lead in 1949, 92 percent was recovered from zinc-lead ore. The output of lead in Arizona in 1949 was far greater than in any

previous year in the State's history. Continuous operations at lead and zinc-lead mines throughout 1949 resulted in a total production of 33,568 tons of recoverable lead, a gain of 3,669 tons over the record output in 1948. The Copper Queen mine of the Phelps Dodge Corp. at Bisbee, with an increase of 23 percent in lead production, remained by far the largest producer of lead in Arizona. Other large producers were the St. Anthony property at Tiger, the San Xavier (Eagle-Picher Mining & Smelting Co.) south of Tucson, the Iron King mine at Humboldt, and the Flux-January-Norton group near Patagonia. More than 92 percent of the lead output in 1949 was recovered from zinc-lead ore and the rest largely from lead ore.

Although the sharp drop in base-metal prices caused some Colorado mines to close in 1949, the State output of lead increased for the third successive year and was the highest since 1927. The five leading producing mines, in order of rank, were the Victory group at Kokomo, Resurrection at Leadville, Treasury Tunnel-Black Bear in San Miguel County, Smuggler Union at Telluride, and Eagle mine at Red Cliff. Zinc-lead ore yielded 65 percent of the State total lead during the year. Lead production in Montana in 1949 declined 2 percent from the 1948 figure. As in most other producing areas, the drop in output was largely the result of declining base-metal prices, which forced closing of some smaller properties and brought about curtailed activity at other operations. At the Butte properties of the Anaconda Copper Mining Co. a 5-day workweek went into effect early in June, underground mining was reduced, shipments of zinc-lead dump ore ceased, and work on the Greater Butte project was temporarily suspended. In mid-November shipments of dump ore were resumed. The four leading lead producers, which supplied 79 percent of the State lead in 1949, were the Butte Hill mine and dumps at Butte, the Emma mine at Butte, the Mike Horse mine at Flesher, and the Jack Waite mine in Sanders County. Lead output from Nevada mines in 1949 surpassed the 1948 production by 9 percent to reach the highest level since 1936. The Pioche district, Lincoln County, accounted for 62 percent of the lead produced in the State in 1949; the leading properties were: The Pioche groups operated by the Combined Metals Reduction Co., the Ely Valley mine worked by Ely Valley Mines, Inc., and the Prince mine of the Prince Consolidated Mining Co. Important producers in addition to those in the Pioche district included the Copper Canyon Mining Co. Copper Canyon mine, Battle Mountain district, Lander County; L. F. Jacobson, Yellow Pine mine, Yellow Pine district, Clark County and McFarland & Hullinger, Cleveland mine, Delano district, Elko County. The California mine production of recoverable lead was 10,318 tons in 1949, a 13-percent gain over 1948 and the highest recorded since the record output in 1917. The Anaconda Copper Mining Co. Darwin group of mines in the Coso district, Inyo County, continued to be the State's leading producer of lead. The property was closed during July, August, and part of September owing to falling base-metal prices in the second quarter of the year. Other important lead mines operated in California in 1949 included Anaconda's Shoshone group, also in the Coso district, the Defense and Minnietta mines in the Modoc district of Inyo County, and the Coronado Copper & Zinc Co. Afterthought mine in the Cow Creek district of Shasta County

Despite a work stoppage most of the year at the Grandview mine of the American Zinc, Lead & Smelting Co. in the Metaline district, normally the State's largest lead producer, lead output in Washington in 1949 was only 10 percent under the 1948 figure. The Bonanza mine in Stevens County and the property of the Pend Oreille Mines & Metals Co. in the Metaline district reported substantial increases in lead yield. Production dropped at the Deep Creek mine in Stevens County. The above four properties supplied 97 percent of the State lead in 1949, and of the total lead 64 percent was derived from zinc-lead ore and nearly all the remainder from lead ore. The mine production of lead in New Mexico, the bulk of which comes from mines yielding chiefly zinc, declined 39 percent from 1948. The larger producers in 1949 were the American Smelting & Refining Co. Ground Hog and United States Smelting, Refining & Mining Co. Bayard groups in the Central district and the Kelly group (American Smelting & Refining Co.) and Lynchburg (S. S. Elayer) in the Magdalena district.

Mine production of recoverable lead in the United States, 1940–44 (average) and 1945–49, by States, in short tons

Mine production of lead in States east of the Mississippi River came from properties in Illinois, Kentucky, New York, Tennessee, Virginia, and Wisconsin and totaled 9,755 tons, a drop of 9 percent from the 1948 output. Reduced production from the Austinville mine of the New Jersey Zinc Co. in Virginia accounted for most of the decrease. The principal lead producers in this region were the New

Jersey Zinc Co. of Virginia, Ozark-Mahoning Co. in Southern Illinois, St. Joseph Lead Co. in New York, and the Tri-State Zinc Co. in Northern Illinois. Lead was also recovered from ores mined in Oregon, South Dakota, and Texas. Virtually all the 51 tons of lead produced in Alaska in 1949 was recovered from the output of the Riverside mine near Hyder in the Southeastern Alaska region.

Mine production of recoverable lead in the United States, by districts that produced 1,000 tons or more during any year, 1940–44 (average) and 1945–49, in short tons

SMELTER AND REFINERY PRODUCTION

Pig lead produced in the United States is derived from three main sources—domestic mine production, imports of foreign ores and base bullion, and secondary smelter output from scrap material, and is recovered at primary plants that treat ore, base bullion, and small quantities of scrap and at secondary plants that process scrap exclusively. Of the eight primary smelters operating in the Western States, only two (Selby, Calif., and Bradley, Idaho) produce refined merchant lead. The other six plants produce only base bullion (containing approximately 98 percent lead plus gold, silver, and small quantities of impurities recovered from the ore smelted), which is shipped to refineries in the Middle Western and Eastern States for recovery of the gold and silver and purification of the lead to meet commercial requirements. Both primary and secondary smelting plants may make refined lead or antimonial lead. Because of the large quantity of hard lead—such as battery scrap—melted at secondary smelters, the output from this type of operation is essentially antimonial lead alloys. Statistics on the production of refined lead and

alloys at secondary plants are given in the Secondary Lead section of this chapter. Of the 14 primary smelters and refineries in operation in the United States in 1949, all but 1 consumed primary raw materials in the form of ores and concentrates. During the year these 13 plants consumed 467,128 short tons (lead content) of this type of material, 16 percent of which was of foreign origin. In 1948 these same plants treated 432,543 tons of ores and concentrates, 16 percent of which was foreign.

ACTIVE LEAD SMELTERS AND REFINERIES

Primary lead smelters and refineries operating in the United States in 1949 were as follows:

California: Selby—Selby plant, American Smelting & Refining Co. (smelter and refinery).
Colorado: Leadville—Arkansas Valley plant, American Smelting & Refining Co. (smelter).
Idaho: Bradley—Bunker Hill Smelter, Bunker Hill & Sullivan Mining & Concentrating Co. (smelter and refinery).
Illinois: Alton—Federal plant, American Smelting & Refining Co. (smelter and refinery).
Indiana: East Chicago—U. S. S. Lead Refinery, Inc. (refinery).
Kansas: Galena—Galena plant, Eagle-Picher Co. (smelter and refinery).
Missouri: Herculaneum—Herculaneum plant, St. Joseph Lead Co. (smelter and refinery).
Montana: East Helena—East Helena plant, American Smelting & Refining Co. (smelter).
Nebraska: Omaha—Omaha plant, American Smelting & Refining Co. (refinery).
New Jersey: Barber—Perth Amboy plant, American Smelting & Refining Co. (smelter and refinery).
Texas: El Paso—El Paso plant, American Smelting & Refining Co. (smelter).
Utah:
  Midvale—Midvale plant, United States Smelting, Refining & Mining Co. (smelter).
  Murray—Murray plant, American Smelting & Refining Co. (smelter).[2]
  Tooele—Tooele plant, International Smelting & Refining Co. (smelter).

REFINED LEAD

Primary refineries in the United States in 1949 produced 500,568 short tons of refined lead, an increase of 22 percent over the 1948 output of 411,646 tons.

Refined lead produced at primary refineries in the United States, by sources, 1945–49, in short tons

Source	1945	1946	1947	1948	1949
Refined lead:					
From domestic ores and base bullion	356,535	293,309	381,109	339,413	404,449
From foreign ores	86,932	44.790	59,838	60,829	71,413
From foreign base bullion	118	98	63	6,452	1,476
Total from primary sources	443,585	338,197	441,010	406,694	477,338

Average sales price per pound	\$0.064	\$0.084	\$0.143	\$0.179	\$0.158
Total calculated value of primary refined lead [1]	\$55,780,000	\$56,820,000	\$126,130,000	\$145,600,000	\$150,840,000

[1] Excludes value of refined lead produced from scrap at primary refineries.

[2] Closed for lack of ore and other economic factors on October 1, 1949.

Of the 477,338 tons of primary lead produced in 1949, domestic ores and base bullion supplied 85 percent and foreign ores and imported base bullion 15 percent. In 1948 the origin was 83 percent domestic and 17 percent foreign. The following tables give the production of refined lead by sources and by country of origin of the ore. Details of the sources of lead from domestic ores are given in the Mine Production section of this chapter.

Refined primary lead produced in the United States, by country of origin, 1945–49, in short tons

ANTIMONIAL LEAD

Antimonial lead output at primary refineries in 1949 dropped sharply from the record level established in 1948. Production increased at only one of the five primary plants producing this alloy, whereas at the other plants declines of 50 to 92 percent from the 1948 outputs were recorded. Distribution of the lead according to source is shown in the following table. The average antimony content of antimonial lead produced in 1949 advanced to 8.2 percent, the highest average content recorded since 1941. Although antimonial lead is an important byproduct of the refining of base bullion, the quantity derived from this source is only a small part of the annual domestic output. The major production is recovered from the smelting of antimonial lead scrap at secondary smelters. Production data from lead-smelting plants treating scrap materials exclusively are summarized in the following section and discussed in detail in the Secondary Metals—Nonferrous chapter of this volume.

Antimonial lead produced at primary lead refineries in the United States, 1945–49

Year	Production (short tons)	Antimony content		Lead content by difference (short tons)			
		Short tons	Percent	From domestic ore	From foreign ore	From scrap	Total
1945	56,495	4,148	7.3	7,286	2,695	42,366	52,347
1946	50,480	3,285	6.5	11,196	2,149	33,850	47,195
1947	86,075	4,933	5.7	14,836	9,850	56,456	81,142
1948	100,764	5,760	5.7	29,561	15,918	49,525	95,004
1949	41,402	3,385	8.2	692	4,620	32,705	38,017

SECONDARY LEAD

Some scrap lead is treated at primary smelters and refineries, but the greater part is received at a large number of plants that treat secondary materials exclusively. Secondary lead is recovered in the form of refined lead, antimonial lead, and other alloys. Recovery at primary and other plants in 1945–49 is shown in the following table. Secondary lead recovery in 1949 surpassed the domestic mine output of recoverable lead for the fourth successive year. Further details appear in the Secondary Metals—Nonferrous chapter of this volume.

Secondary lead recovered in the United States, 1945–49, in short tons

	1945	1946	1947	1948	1949
As refined metal:					
At primary plants	18,525	8,013	15,662	4,952	23,230
At other plants	42,598	65,691	95,843	126,951	129,396
Total	61,123	73,704	111,505	131,903	152,626
In antimonial lead:					
At primary plants	42,366	33,850	56,456	49,525	32,705
At other plants	151,713	159,834	209,479	194,027	140,037
Total	194,079	193,684	265,935	243,552	172,742

LEAD PIGMENTS

The principal lead pigments are litharge, white lead, red lead, sublimed lead, leaded zinc oxide, and orange mineral. These products are manufactured for the most part from metal, but some ore and concentrates are converted directly to pigments. Details of the production of lead pigments are given in the Lead and Zinc Pigments and Zinc Salts chapter of this volume.

CONSUMPTION AND USES

Domestic lead consumption (including lead in lead ore used directly in the manufacture of lead pigments and salts) totaled 957,674 short tons in 1949. Of the total consumed, 592,682 tons were refined soft lead, 227,221 tons antimonial lead, 50,922 tons unmelted white scrap, 46,268 tons percentage metals, 15,976 tons copper-base scrap, 15,215 tons drosses and residues, and 9,390 tons from lead ores used directly

in the manufacture of lead compounds. During the year 77 percent of the total lead consumed was used in the manufacture of metal products. Production of the three largest lead-consuming items—batteries, cable covering, and tetraethyl fluid—used nearly 58 percent of all the lead consumed in 1949. Batteries took 33 percent of the total, cable covering 15 percent, and tetraethyl fluid 10 percent.

Consumption of lead in the United States in 1948 and 1949, in short tons

[1] Excludes 9,390 tons of lead contained in leaded zinc oxide.

STOCKS

Producers' Stocks.—Lead stocks, as reported by the American Bureau of Metal Statistics, are shown in the following table. Stocks of refined and antimonial lead include metal held by all primary refiners and by some of the refiners of secondary material who produce soft lead. According to monthly reports released by the American Bureau of Metal Statistics, stocks of refined lead and antimonial lead declined in the first 2 months of the year to a low of 36,101 tons at the end of February. Inventories gained sharply to 53,422 tons during March and continued to advance through April, May, and June to the peak 1949 level of 96,367 tons on July 1. Stocks declined slightly during July and dropped sharply in August and September to 60,208 tons on October 1. During the remainder of the year the inventories advanced steadily to 70,424 tons on December 31—a net gain of 82 percent from January 1.

Lead stocks at end of year at smelters and refineries in the United States, 1945–49, in short tons

[American Bureau of Metal Statistics]

	1945	1946	1947	1948	1949
Refined pig lead	37,584	40,870	13,634	29,050	61,329
Antimonial lead	7,283	6,717	7,694	9,594	9,095
Total	44,867	47,587	21,328	38,644	70,424
Lead in base bullion—					
At smelters and refineries	8,618	8,453	7,652	9,697	16,364
In transit to refineries	4,889	4,911	5,447	4,101	3,696
In process at refineries	15,097	16,042	16,328	17,939	15,561
Total	28,604	29,406	29,427	31,737	35,621
Lead in ore and matte and in process at smelters	89,462	111,836	77,199	76,373	95,481
Grand total	162,933	188,829	127,954	146,754	201,526

The Bureau of Mines annual survey of primary lead smelters and refiners indicated stocks of 29,048 tons (lead content) of refined lead at plants on January 1, 1949, and 60,826 tons on December 31, 1949. Primary antimonial lead stocks at these same plants decreased from 9,258 short tons (lead content) at the beginning of 1949 to 8,192 tons at the end of the year. In terms of lead content, stocks of ore and concentrates at the operating primary smelters and refineries increased 40 percent—from 44,038 tons to 61,736 tons during the same period. The inventory of base bullion at refineries that receive base bullion as a raw material and at smelters that produce base bullion for shipment to refineries totaled 7,743 tons at the beginning of January and 7,897 tons at the end of December 1949. The revised figure for January 1, 1948, is 7,728 tons. Stocks of in-process base bullion or work lead at five combination smelter-refinery plants are not included in reports to the Bureau of Mines. No direct comparison can be made between these data and the figures of the American Bureau of Metal Statistics. Figures reported to the Bureau of Mines represent physical inventory at the plants, irrespective of ownership, and do not include material in process or in transit.

Consumers' Stocks.—Consumers' stocks of lead decreased 18 percent during 1949. Inventories of refined lead gained 4 percent, but antimonial lead dropped 52 percent from the January 1 level. Total stocks, which on January 1, 1949, were 119,198 tons, advanced to 136,855 tons on March 31 and thereafter declined steadily to 97,267 tons on December 31.

Consumers' stocks of lead at the end of year, 1947–49, by types of materials, in short tons

Date	Refined soft lead	Antimonial lead	Unmelted white scrap	Percentage metals	Copper-base scrap	Drosses, residues, etc.	Total

Dec. 31, 1949	64,542	16,837	2,957	5,405	2,087	5,439	97,267

PRICES

The two major markets for lead in the United States are New York and St. Louis; much of the lead produced domestically is sold at prices normally based upon quotations in these markets. Since suspension of trading on the London Metal Exchange in September 1939, the London market has had no direct influence on New York quotations, and the differential between St. Louis and New York prices has remained 0.2 cent a pound, an amount approximating the freight charges between the two points.

The market price for common lead, New York, was quoted at 21.50 cents a pound until March 8, when it dropped to 19.50 cents. A series of price reductions followed thereafter until the quotation reached a low of 12.00 cents on May 26. A 1-cent increase occurred on July 8, and several additional increases established the quotation at 15⅛ cents on August 18. The price trended downward beginning September 26 and leveled off at 12.00 cents on November 21, where it remained the balance of the year.

The price of the British Ministry of Supply was £123 per long ton (equivalent to 22.10 cents a pound) at the beginning of 1949. On April 4 the price was reduced to £106 (19.05 cents) and on May 16, June 10, and July 12, further reductions to £95 (17.07 cents), £82 (14.73 cents), and £75 10s. (13.57 cents), respectively, took place. It was raised shortly thereafter to £81 (14.55 cents) on July 14 and continued to advance in three successive increases to £87 5s. (15.68 cents) on August 9. In mid-September the British pound was devalued, and price quotations were suspended for a few days. On September 22 the sterling price was £122 per long ton (equivalent to 15.25 cents a pound at the new $2.80 base). A reduction to £115 (14.38 cents) was announced, effective October 5 and on October 12 and 19 the price dropped to £111 (13.88 cents) and £105 (13.12 cents), respectively. A further decline to £97 (12.12 cents) occurred on November 23, at which level the quotation remained for the balance of the year.

Average monthly and yearly quoted prices of lead at St. Louis, New York, and London, 1947–49, in cents per pound [1]

FOREIGN TRADE [3]

Tariff.—The import duty set by the Tariff Act of 1930 on lead-bearing ores, flue dust, and mattes (lead content) was $1\frac{1}{2}$ cents per pound and on lead bullion, pigs, bars, scrap lead, antimonial lead, type metal, babbitt metal, solder, and alloys not specifically provided for, $2\frac{1}{8}$ cents per pound. In accordance with the Mexican Trade Agreement of January 30, 1943, these rates were reduced to $\frac{3}{4}$ cent and $1\frac{1}{16}$ cents per pound, respectively. In June 1948 these duties were suspended for 1 year by act of Congress. As the Congress took no action on a bill to extend the suspension beyond June 30, 1949, the expiration date of the original legislation, the import duty of $1\frac{1}{16}$ cents a pound on pig lead and $\frac{3}{4}$ cent a pound on lead in ores and concentrates was reinstated automatically on July 1.

Imports.—Total imports of lead increased in 1949 to a record peacetime high but remained well below the wartime peak level established in 1942. As in previous years, the greater part of the lead imported was in the form of pigs and bars, 46 percent of which came from Mexico, 20 from Canada, 13 from Peru, 9 from Yugoslavia, 6 from Australia, and 6 from 17 other countries. Imports of lead in base bullion, virtually all from Australia, were approximately one-third the quantity imported in 1948. Receipts of lead in ore, concentrate, and matte, principally from Africa, Bolivia, Peru, Australia, Newfoundland, and Mexico, were the largest since 1940.

[3] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Total lead imported into the United States in ore, matte, base bullion, pigs, bars, and reclaimed, by countries, 1945–49, in short tons [1]

[3] Less than 1 ton.

WORLD REVIEW

Lead is produced in many countries, but four—United States, Mexico, Australia, and Canada—have accounted for nearly three-quarters of the world output in recent years, as is apparent from the accompanying tables, which show world mine and smelter production by countries, 1943–49, insofar as statistics are available.

World mine production of lead, by countries, 1943–49, in metric tons [1]

Country	1943	1944	1945	1946	1947	1948	1949
Algeria	400	1,100	200	1,000	1,300	1,044	1,057
Argentina	17,700	20,000	18,200	18,100	20,900	21,800	16,000
Australia	209,700	192,500	167,300	186,700	199,800	207,776	203,445
Austria	(2)	(3)	1,272	981	1,528	3,007	4,297

[2] Includes scrap.

[3] Data not yet available; estimate by author of chapter included in total.

[4] Included with Germany.

[5] Exclusive of secondary material. Includes Upper Silesia and Sudetenland through 1944.

[6] Estimate.

[7] American and British zones only.

[8] January to June, inclusive.

[9] Data represent Trianon Hungary after October 1944.

[10] Figures cover lead refined from domestic and foreign ores; refined lead produced from foreign base bullion not included.

Argentina.—The chief lead-producing district in Argentina is the Aguilar, where the Compania Minera Aguilar, S. A., a subsidiary of the St. Joseph Lead Co., operates the Aguilar group of mines. Production in 1949 was at a rate approximately 40 percent under the installed mill capacity due to continued difficulty of obtaining adequate transportation facilities to maintain incoming shipments of machinery, Diesel oil, mine timber, and miscellaneous supplies, as well as shipments of concentrates to the smelter. The output of lead concentrates in 1949 totaled 19,142 metric tons compared with 24,068 tons in 1948. Lead concentrates from the Aguilar mine are smelted at the National Lead Co., S. A., smelter at Barranquera, Chaco Territory, which also treats lead ores and concentrates imported from Bolivia.

Australia.—Although most lead producers reported increased outputs in 1949, transportation difficulties and shortages of steel and skilled labor continued to restrict production.

As in previous years, the famous Broken Hill lode in New South Wales accounted for a substantial portion of Australian lead production in 1949. Output from the northern limb of the lode, operated by the North Broken Hill, Ltd., increased slightly over 1948, despite the company's continued difficulty in obtaining skilled mine labor. A total of 327,205 tons of ore was mined, most of which assayed 15.0 percent lead, 12.3 percent zinc, and 7.5 ounces of silver per ton. Nearly 330,000 tons of ore were milled, but owing to an increased quantity of partly oxidized ore in the mill feed, recoveries of lead and zinc in the concentrates dropped slightly from the record achieved in 1948. At Broken Hill South, Ltd., on the southern limb of the lode, production for the year ended June 30, 1949, totaled 267,028 tons of ore assaying 12.9 percent lead, 12.2 percent zinc, and 7.4 ounces of silver per ton, from which 44,314 tons of lead concentrates containing 74.5 percent lead were recovered. Other companies operating in the Broken Hill area in 1949 included the Zinc Corp., Ltd., and the New Broken Hill Consolidated, Ltd.

The Lake George Mining Corp., Ltd., at Captain's Flat, New South Wales, was in full operation only 67 days in the year ended June 30, 1949, due to a labor strike which began on October 12, 1948, and to a strike of coal miners in New South Wales.

Lead and zinc production continued to be emphasized at the Mount Isa mines in northwest Queensland in 1949. Some difficulty was experienced in obtaining adequate rail transportation facilities and maintaining an adequate supply of coal for the company steam power plant. The copper section of the mine remained idle pending completion of the new copper milling and smelting plant that is expected to treble Queensland's copper production.

In the Read-Rosebery district of Tasmania, from which approximately 4 percent of the Australian lead production is derived, the Electrolytic Zinc Co. of Australasia continued to operate its Rosebery and Hercules mines. The Rosebery ore averages 21.3 percent zinc, 6.4 percent lead, 0.5 percent copper, 8.5 ounces of silver, and 2.1 dwt. gold per ton; ore at the Hercules mine averages slightly higher in grade. Ore from both properties is treated at the company mill at Rosebery. Lead concentrates produced are exported to the United States for treatment.

Bolivia.—The largest producer of lead, as well as silver and zinc, in Bolivia is the mine of the Cia. Huanchaca de Bolivia at Pulacayo in the Tupiza lead mining region. Ore from this mine, which has been worked more than 100 years, contains 1.5 percent lead, 3.5 percent zinc, 0.5 percent copper, and 15 ounces of silver per ton; it is treated in the company 1,000-ton per day selective flotation mill. The remainder of Bolivia's lead output is obtained from a number of small operators employing primitive hand methods of mining and concentrating. As there is no lead smelter or refinery in Bolivia, all ores and concentrates must be exported for further treatment. Banco Minero, a Bolivian Government subsidiary which by law controls the ore-buying business, began construction during 1949 of a small lead smelter near La Paz designed to treat 5 tons of lead concentrates per day. If

operation of this smelter proves successful, the Government will build near Tupiza a 20-ton-per-day smelter capable of processing both ores and concentrates. The problem of maintaining adequate fuel supplies for both smelters has not been solved. Coke is being imported for the smelter near La Paz.

Burma.—Rehabilitation of the war-damaged Burma Corp., Ltd., Bawdwin mine progressed slowly in 1949. The mine was unwatered to a depth somewhat below the No. 12 level, and ore was extracted for the first time since Japanese occupation. However, due to intensified insurgent activities beginning in the early part of the year, which completely immobilized rail connections with Rangoon and Mandalay, the company was forced to discontinue operations in March after reaching a peak monthly mine output of 2,350 tons. The operators have reported [4] that, until rail traffic can be resumed, the mine and smelter are on standby basis. A crew of skilled personnel has been retained to keep the plant and property in working order. Negotiation with the Government of the Union of Burma continued in the early part of 1950 for renewal of the Bawdwin lease which expired December 31, 1949.

Canada.—At Kimberley, British Columbia, the Sullivan mine of the Consolidated Mining & Smelting Co. continued to be the principal source of Canadian lead. Ore production in 1949 totaled 2,297,672 tons compared with 2,283,625 tons in 1948. The company reports [5] that the grade of ore was lower in 1949 due to more extensive pillar mining and the resulting dilution of ore, in addition to mining a greater tonnage of low-grade material to effect higher over-all metal recovery from the mine. New facilities installed and put into operation in 1949 include the underground crushing plant, 3,700-foot level adit and haulageway to the mill, and sink-float plant. Treatment of ore in the sink-float plant was begun in May; approximately 2,000 tons of waste are rejected by this operation daily. Concentrates from the Sullivan mine were treated at the company smelter at Trail, B. C., with ores and concentrates received from 97 other mining properties in Canada, United States, Asia, Australia, and South America. Production of pig lead at this smelter, the only lead smelter and electrolytic lead refinery in Canada, dropped from 160,107 tons in 1948 to 146,176 tons in 1949. Completion of a second slag-fuming furnace in August made possible treatment of all current lead-blast-furnace slag and zinc-plant residues, as well as substantial quantities of these materials accumulated in past years. A program outlining certain changes in lead-smelting techniques was announced during the year. The present method of blending ores, fluxes, and concentrates is to be replaced, a new sintering plant is to be built, and new facilities for handling slag and lead bullion are to be provided.

Other lead producers in British Columbia include Canadian Exploration, Ltd., which began milling silver-lead-zinc ore from its Jersey property south of Salmo in January; the Torbrit Silver Mines, Ltd., at Alice Arm; the Silver Standard property at Hazelton; Base Metals Mining Corp., Ltd., near Field; and the Highland-Bell Ltd., at Beaverdell.

[4] Burma Corp., Ltd., 1949 Annual Report to Stockholders.
[5] Consolidated Mining & Smelting Co., 1949 Annual Report to Stockholders.

The Buchans Mining Co. Ltd., Newfoundland, reported [6] discovery of new lead-zinc ore bodies northwest of the Lucky Strike mine, which will prolong the life of the property until 1960.

Chile.—Lead production was reported in 1949 from the Compania Minera Aysen mine on the north shore of Lago Buenos Aires in Aysen Territory of southern Chile. Construction of a 60-ton-per-day lead-zinc flotation mill was begun during the year and scheduled for completion in mid-1950. Because of poor transportation facilities to Chilean ports, the ore produced in 1949 was sold to an Argentine subsidiary of the French Peñarroya Co. for treatment at the lead smelter at Barranqueras, Chaco Territory.

France.—The lead refinery of the Société Min. et Met. de Peñarroya in southern France was put back into production during 1949 to treat lead bullion recovered at the Peñarroya-Zellidja smelter at Oued-el-Heimer in French Morocco.

French Morocco.—The most important lead mine in French Morocco is the Bou-Bekar property 50 kilometers southeast of Oujda, on the Algerian-Moroccan border, and operated by Société Nord Africaine du Plomb. This company is owned jointly by Société des Mines de Zellidja (51 percent), Newmont Mining Corp. (33 percent), and St. Joseph Lead Co. (16 percent). French-American technical collaboration, financed in part by an advance of funds through the Marshall Plan, has made modernization and expansion of this property possible. Improvements include a new concentrating mill, additional equipment within the mine, a new smelter, additional facilities for generating electric power, new dwellings for employees, and a new access road. By 1954 it is expected that mine production will reach 60,000 metric tons of lead metal and 60,000 tons of zinc metal annually.

Greece.—During 1949 an application for a European Cooperation Administration industrial loan was filed by the General Mining Co. of Greece. Funds made available will be used to finance exploration of lead-zinc outcrops on the island of Chios. Deposits on the islands of Samothrake and Thasos were also to be examined. At the French Laurium mines work on three new mine headings was under way to increase the output of high-grade lead-zinc ores. The Kirka mine in northern Greece was leased during the year by Mediterranean Mines, Inc., a subsidiary of Ventures, Ltd.

Greenland.—A Danish Government geological survey party returned to Greenland in the summer of 1949 for further study of the lead deposits on the east coast at Mesters Vig in the area around King Oscar Fjord and Davy Sound. Results of the survey were not announced nor were any plans for exploitation of the deposit. The survey party which discovered the deposit in the summer of 1948 reported ore samples assaying 80 percent lead and 300 grams of silver per ton. The deposit is thought to contain 1 million tons of lead.

Mexico.—Problems of mine taxation, rail freight rates, and deficient rail service continued burdensome to Mexican mine operators in 1949. Compared with 1948, the labor disputes were relatively few and quickly settled. During the year the American Smelting & Refining Co. completed its New Taxco, Guerrero, unit mill at a cost

[6] American Smelting & Refining Co., 1949 Annual Report to Stockholders.

of $1,000,000. The 800-ton daily capacity zinc-lead flotation plant will provide a market for ores from the Taxco area and also from the La Concha region in Guerrero. A diamond-drilling program was undertaken by the American Smelting & Refining Co. at the Nuestra Señora property in the Cosala district, Sinaloa. The company reports [7] development of a worth-while tonnage of lead-zinc ore.

Peru.—The new 330-ton flotation mill of the Compania Minera Atacocha, near Cerro de Pasco, began operations March 5, 1949. The Atacocha mine, owned and managed by Peruvians, is one of the most important lead-silver-zinc producers in Peru. Increased production from the Huachocolpa region was anticipated with completion of the Banco Minero del Peru 100-ton sink-float plant and 50-ton concentration mill. In the Chiquian mining region in the Department of Ancash, lack of access roads continued to delay development of properties. A 20-ton mill was recently installed in the region by Compania Argento Bolognesi. A 150-ton flotation plant was installed at the Empresa Minera Huamachuco property in the Department of La Libertad. Mills were also installed at the Caudalosa mine near Castrovirreyna, inland from Pisco, and at the north Peruvian mine operated by the Compania Minera Tarica.

Tanganyika.—Uruwira Minerals, Ltd., continued to develop its lead deposit at Mpanda. The main shaft was sunk to 1,200 feet and exploration pushed ahead at various levels. Approximately 5,000,000 tons of ore averaging 6.48 percent lead, 0.61 percent copper, 118.7 grams of silver, and 2.1 grams of gold per ton are reported [8] to have been developed as a result of current investigations. A pilot plant capable of treating 100 tons of ore per day was installed during the year. Lead concentrates produced at the mill will be stockpiled until completion of the railway link between Mpanda and Kaliua, on the Central Line of the Tanganyika Railways west of Tabora. At the end of 1949 completed track extended 138 kilometers from Kaliua, leaving 72 kilometers to be laid. It is anticipated that work on this line will be completed in 1950.

Lead and Zinc Pigments and Zinc Salts

By Helena M. Meyer and Alethea W. Mitchell

GENERAL SUMMARY

DESPITE diversified movements in industries that are the chief consumers of pigments, there were sharp declines in 1949 in shipments of all of the lead and zinc pigments and zinc salts covered by this report. The decreases in lead pigments ranged from 19 percent for red lead to 41 percent for white lead (dry), in zinc pigments from 27 percent for zinc oxide (lead-free) to 46 percent for the leaded variety; they were 20 and 7 percent, respectively, for zinc chloride and zinc sulfate.

The following trends were noted among the industries that consume large quantities of pigments: Automobile production rose 17 percent to a new all-time peak; total value of construction put in place, both private and public, exceeded $19 billion, surpassing the 1948 record by 3 percent; the value of sales of paints, varnish, and lacquer materials, on the other hand, fell about 9 percent; consumption of natural rubber 8 percent and of the synthetic type 6 percent; and production of synthetic rubber dropped 23 percent, indicating a more pronounced decline in need for pigments than consumption data showed. The relatively greater drop in pigments than in the level of activity in pigment-consuming industries may be explained by a reduction in inventories of pigments at consumers' plants.

Shipments of white lead (dry) dropped 41 percent and of the in-oil variety 40 percent, being the smallest by far for both grades since considerably before the beginning of the present century; total white lead shipments amounted to only 27 percent of the annual average for 1935–39. Litharge shipments declined 22 percent in 1949 and were the smallest since 1943. Red-lead shipments decreased 19 percent, the smallest decline of the pigments covered by this report, and were the lowest since 1933.

Lead-free zinc-oxide shipments dropped 27 percent and were smaller than in any year since 1942, when there were insufficient supplies of zinc metal and scrap for manufacture of the French-process type. The labor strike beginning September 26 and continuing beyond the end of 1949, at the Palmerton plant of the New Jersey Zinc Co., curtailed both production and shipments of the leaded as well as the lead-free grades and likewise reduced tonnages of lithopone. Leaded zinc-oxide shipments fell 46 percent and lithopone 44 percent and were the smallest since 1935 and 1921, respectively.

The World War II and early postwar situation of inadequate supplies of pig lead in relation to consumption requirements was reversed in 1949, when domestic production and peacetime peak imports considerably exceeded demand. Supplies of zinc in 1949 likewise were

more than adequate for all needs. The foregoing situation was due in part to the drop in general industrial activity that began before midyear. This decline was largely counterbalanced by increased industrial activity in the late months of 1949.

Lead-pigment prices reached new peaks in 1947 and 1948 and continued at top levels early in 1949. Zinc-pigment prices likewise were very high during the period. The break in nonferrous metal prices in the spring and early summer of 1949 was accompanied by lower prices for pigments. December prices for lead and zinc both were 44 percent below those for January. Pig lead and lead pigments were at their lowest levels in the second quarter of the year and had substantial recovery in the third; resumption of the downtrend resulted in a return in December to the lowest levels of the year. Slab zinc and zinc pigments followed the same pattern, in general, but were mostly above the year's lowest levels at the end of December.

Zinc-chloride and zinc-sulfate shipments decreased 20 and 7 percent, respectively, and were the lowest since 1943 and 1944, respectively.

Salient statistics of the lead and zinc pigments industry of the United States, 1940–44 (average) and 1945–49

	1940–44 (average)	1945	1946	1947	1948	1949
Production (shipments)[1] of principal pigments:						
White lead (dry and in oil) short tons	87,819	51,170	[2] 66,501	68,787	46,070	27,355
Red lead do	50,351	47,381	32,526	36,064	30,787	24,866

[1] Reported as sales before 1945.
[2] Data for basic lead sulfate in 1946 included under white lead; Bureau of Mines not at liberty to show separately.
[3] Excludes value of basic lead sulfate; Bureau of Mines not at liberty to publish.
[4] Less than $500.

Production and shipments of competitive titanium pigments dropped somewhat from 1948, following the establishment of five successive annual peaks; except for 1948, both items were at the highest

annual rates ever attained. At present the Bureau of Mines is not at liberty to publish figures covering pigments of this class.

Highlights in the distribution of pigments and salts covered by this report are outlined in the following discussion. Shipments of litharge for the manufacture of chrome pigments rose 15 percent in 1949 and made the only advance for pigments covered by this report. This rise, however, followed a poor showing in 1948, when it registered the sharpest percentage drop among litharge uses. The use of pigments in ceramics made conspicuous gains after 1945, but all types of pigments used for this purpose showed substantial losses in this field in 1949. Ceramics—now the second largest use of litharge—established a new peak in 1948 but dropped 33 percent in 1949, or proportionately more than any other important use. Shipments of red lead to makers of ceramics fell more than any other class and amounted to less than one-half of the 1948 tonnage. The use of zinc oxide in ceramics established three successive peaks in 1946, 1947, and 1948 but was reduced 43 percent in 1949 as compared with 27 percent for total zinc-oxide shipments. Zinc oxide and red lead shipped for paint manufacture fared better than other pigments shipped for this purpose. Rubber took proportionately more lithopone in 1949 than in 1948 and except for

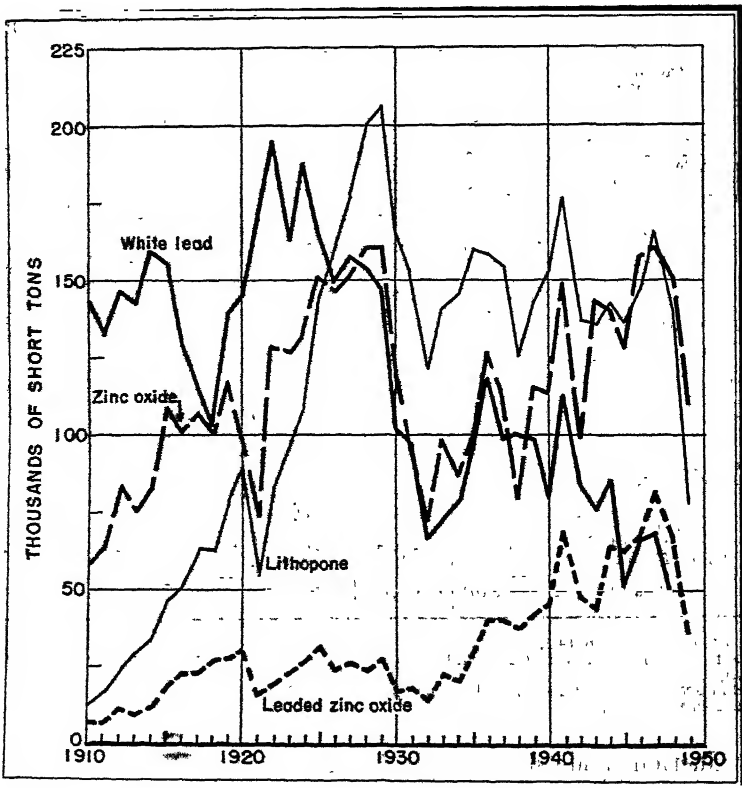

FIGURE 1.—Trends in shipments of white pigments, 1910–49.

1948 used more than in any year since 1941. Shipments of zinc oxide and lithopone for coated fabrics were in contrast in 1949, those of the former falling proportionately more and of the latter less than total shipments of these two classes of pigments. Floor coverings took much less of both pigments in 1949, zinc-oxide shipments falling a much higher percentage than total shipments.

Zinc sulfate made the best showing of the products covered by this report, chiefly because of record-breaking shipments for rayon manufacture, the gain being 9 percent (dry basis) over the previous peak in 1948. The agricultural use, which led all others in 1946, took less than one-half as much as rayon in 1949.

PRODUCTION

The value of lead and zinc pigments in 1949 (exclusive of that for basic lead sulfate, which cannot be shown) was $101,716,000, a decrease of 35 percent compared with a 32-percent decline during 1949 in the total tonnage of the lead and zinc pigments covered. Lead pigments and zinc pigments comprised 58 and 42 percent, respectively, of the total value in 1949 as in 1948.

For many years, figures on sales were used in this series of reports as a better guide than production to activity in the pigments industry. Beginning with 1945, the base was changed to shipments to conform with data compiled on Bureau of Mines lead and zinc schedules. Available information for 1945 (the year of change) indicated that there was little difference between sales and shipments in that year. In reporting tonnages of pigments, an attempt is made to avoid all duplication; one of the chief problems is that finished pigments frequently are blended to make another product. Basic lead sulfate and zinc oxide, for example, are blended to make leaded zinc oxide, and in this instance the pigment weights appear in the total for the last-named class only. Pigments consumed by producing companies to make products beyond those covered by this report—that is, paints, storage batteries, and other articles—are considered as shipments.

LEAD PIGMENTS

Shipments of lead pigments dropped 25 percent in quantity and 36 percent in value in 1949 as compared with 1948. The smaller average values received by producers for all but white lead in oil, which rose slightly, explain the greater decrease in total value than in total quantity. (Shipments of basic lead sulfate, which the Bureau of Mines is not at liberty to publish, are excluded from the figures shown.) All lead pigments covered by this report fell in 1949—shipments of white lead, dry, dropping 41 percent, the in-oil variety 40 percent, litharge 22, and red lead 19.

Quoted prices for lead pigments dropped substantially during the year from the all-time peaks at the year's beginning; average values reported by producers fell 16 percent for both red lead and litharge and 3 percent for white lead (dry), whereas that for the in-oil variety gained 1 percent.

Production and shipments of lead pigments [1] in the United States, 1948–49

Pigment [1]	1948 Production (short tons)	1948 Shipments: Short tons	1948 Shipments: Value [2] Total	1948 Shipments: Value [2] Average	1949 Production (short tons)	1949 Shipments: Short tons	1949 Shipments: Value [2] Total	1949 Shipments: Value [2] Average

[1] Reported as sales before 1945.
[2] Small quantity of orange mineral included with red lead.
[3] Orange mineral included with red lead.
[4] Basic lead sulfate included with white lead (dry); Bureau of Mines not at liberty to publish figure.
[5] Bureau of Mines not at liberty to publish figure.

White Lead.—The downtrend in shipments of white lead, both the dry and in-oil varieties, continued in 1949, and shipments of both varieties were the smallest by far since considerably before the beginning of the present century. The all-time record prices for pig lead in 1947 and 1948, due to stringent supplies of this raw material, were a major factor in sharp extension of the downward movement.

Basic Lead Sulfate.—The Bureau of Mines is not at liberty to publish figures on basic lead sulfate for 1946–49.

Red Lead.—Red-lead shipments fell 19 percent from 1948 and were the smallest since 1933. Nonetheless, red lead had the smallest decline of the pigments covered by this report.

Orange Mineral.—No shipments nor production of orange mineral were reported in 1947–49.

Litharge.—Shipments of litharge dropped 22 percent in 1949 and were the smallest since 1943. Shipments of this pigment, however, were at a higher level than in any year before 1941 and thus ranked highest of the pigments covered by this report.

Lead Suboxide.—Battery manufacturers produced 55,000 short tons of black suboxide of lead for their own use in 1949. This quantity was 20 percent below the high record established in 1947 and continued in 1948. Black oxide production required 53,000 tons of pig lead in 1949 and 66,000 tons in both 1948 and 1947.

ZINC PIGMENTS AND SALTS

Shipments of zinc pigments declined 37 percent in quantity and 34 percent in value in 1949 as compared with 1948; the drop in value was from an all-time peak. All pigments covered shared the decrease—lead-free zinc oxide fell 27 percent, the leaded class 46 percent, and lithopone 44 percent. An increase in the average value received for zinc oxide—the largest tonnage pigment—accounted for the smaller decline in total value than in total quantity. Quoted prices, like those for lead pigments, dropped during 1949 from the high levels prevailing when the year began.

Production and shipments of zinc pigments and salts in the United States, 1948–49

Pigment or salt	1948				1949			
	Production (short tons)	Shipments			Production (short tons)	Shipments		
		Short tons	Value [1]			Short tons	Value [1]	
			Total	Average			Total	Average
Zinc oxide [2]	146,565	150,958	$32,862,368	$218	109,126	110,132	$25,299,970	$230
Leaded zinc oxide [2]	67,480	67,441	16,548,636	245	37,046	36,722	8,874,695	242
Lithopone	151,005	140,033	16,135,976	115	72,233	78,335	8,977,178	115
Zinc chloride, 50° B	67,908	68,701	4,717,963	69	55,197	55,208	3,857,386	70
Zinc sulfate	20,125	21,513	2,443,869	114	20,952	20,065	2,365,120	118

[1] Value at plant, exclusive of container.
[2] Zinc oxide containing 5 percent or more lead is classed as leaded zinc oxide. In this table data for leaded zinc oxide include a small quantity containing less than 5 percent lead.

Zinc chloride shipments were 20 percent lower than in 1948, believed to be the all-time record. The average value was slightly higher in

1949. Zinc sulfate shipments had a 7-percent drop—the smallest decline of the products covered by this report. The average value received by producers rose 4 percent in 1949.

Zinc pigments and salts shipped [1] in the United States, 1910–49, in short tons

[1] Reported as sales before 1945.
[2] No canvass.
[3] Figures represent production.
[4] Data not available.

Zinc Oxide.—Production of lead-free zinc oxide totaled 109,126 tons, or 26 percent less than for 1948. Lead-free zinc oxide shipments dropped 27 percent in 1949 and were the smallest since 1942, when the output was affected adversely by stringent supplies of zinc metal and scrap. Production in 1949 was curtailed by the labor strike beginning September 26 and lasting beyond the end of the year at the Palmerton, Pa., plant of the New Jersey Zinc Co.

Production of zinc oxide (lead-free) by processes, 1944–49, in percent of total

Process	1944 [1]	1945 [1]	1946 [1]	1947	1948	1949
American process (ore and primary residues)	77	77	75	73	76	71
French process (metal and scrap)	16	15	17	17	15	17
Other	7	8	8	10	9	12
Total	100	100	100	100	100	100

[1] Revised figures.

Leaded Zinc Oxide.—The 1949 production of leaded zinc oxide was reported, by grades, as follows (comparison with 1948 in parentheses): 31,434 (53,915) tons of 35 percent lead and under, and 5,612 (13,565) tons of over 35 percent lead. The strike at the Palmerton, Pa., plant of the New Jersey Zinc Co., already mentioned under Zinc Oxide, likewise curtailed output of the leaded variety.

Leaded zinc oxide shipments fell 46 percent in 1949, following a long period, roughly coinciding with the beginning of World War II through 1948, during which peak or near peak tonnages were distributed. The good performance during the years before 1949 was permitted by the fact that leaded zinc oxide is made largely from ores, so that inadequate supplies of metal and scrap during the period under discussion did not militate against the manufacture of this pigment.

Lithopone.—Lithopone fared worse in 1949 than most other pigments covered by this report. Shipments dropped 44 percent—a smaller percentage than those of leaded zinc oxide—but were the lowest since 1921 and only 38 percent of the peak shipments in 1929. Plant capacity for the manufacture of lithopone was reported to be 157,000 short tons in 1949, unchanged from 1948 and 1947.

The lithopone statistics in this report are given on the basis of ordinary lithopone sold as such plus the ordinary lithopone content of the high-strength product. This method of publication is used to conceal the operations of one company that always dominates the output of the high-strength product and has been the only producer in some years. In 1949, as in 1948 and 1947, one company operating two plants produced high-strength lithopone. Consumption of ordinary lithopone in the manufacture of titanated lithopone has dropped to very small proportions. The trend has been downward almost continuously since the peak—19,400 tons—was used in 1937. In 1949 the tonnage was unchanged from the small total for 1948. The lithopone figures in the following table are included in the totals for ordinary lithopone in other tables.

Titanated lithopone produced in the United States and ordinary lithopone used in its manufacture, 1940–44 (average) and 1945–49, in short tons

Year	Titanated lithopone produced	Ordinary lithopone used	Year	Titanated lithopone produced	Ordinary lithopone used
1940–44 (average)	13,240	11,180	1947	2,600	2,200
1945	9,200	7,800	1948	2,100	1,700
1946	7,500	6,350	1949	2,000	1,700

Zinc Sulfide.—In 1949, as in several preceding years, only one company produced zinc sulfide; the Bureau of Mines is not at liberty to publish figures for this pigment.

Zinc Chloride.—Zinc chloride shipments (50° B. solution) dropped 20 percent in 1949 from 1948 (believed to have been the all-time peak). The figures shown here include the zinc chloride equivalent of zinc ammonium and chromated zinc chloride produced.

Zinc Sulfate.—Shipments of zinc sulfate decreased 7 percent in 1949, the smallest decline in the products covered by this report. The tonnages for 1948 and 1947, almost identical, were second only to the all-time record established in 1946.

RAW MATERIALS USED

Figures covering the raw materials used in making pigments and salts in 1949 and 1948 are shown in the accompanying tables.

Lead pigments and zinc pigments and salts are manufactured from a variety of materials, including ore, refined metal, and such secondary materials as scrap. In 1949 roughly 94 (92 in 1948) percent of the lead in pigments was derived from pig lead and the remainder from ore. Of the lead in ore used to make leaded zinc oxide, about 6 (7) percent was from foreign sources. The proportion for zinc pigments in 1949 was 72 (73) percent from ore and concentrates, 8 (8) percent from slab zinc, and 20 (19) percent from secondary materials; about 18 (19) percent of the ore used was foreign.

The following tables give the source of the metal used in manufacturing each pigment and salt. Pig lead is employed exclusively, either directly or indirectly, in the manufacture of white lead, litharge, red lead, and orange mineral and is used also in the manufacture of basic lead sulfate. The lead content of leaded zinc oxide made from basic lead sulfate, which in turn was made from pig lead, is credited to pig lead in the table. Zinc oxide is the only pigment in which considerable slab zinc is used. Ore is employed in the manufacture of zinc oxide, leaded zinc oxide, lithopone, zinc sulfide, zinc sulfate, and basic lead sulfate. A substantial proportion of the zinc in lithopone (65 percent in 1949 and 63 in 1948) and most of that in zinc chloride (all in 1949 and 1948) made in the United States are derived from secondary material. For a number of years before the United States entered the recent World War, there had been a large increase in the quantity of secondary zinc used in the manufacture of zinc oxide. The scarcity of supplies of both metal and scrap caused the proportion of the total oxide made by the French process, which uses only metal and scrap, to drop sharply in 1942 and to continue comparatively low in 1943–46, despite the fact that the percentage from metal and scrap rose in 1943 and continued upward almost without interruption in 1944–49. The production of zinc oxide from metal and scrap accounted for the following percentages in relation to total production: 41 percent in 1939, 16 percent in 1942, 19 percent in 1943, 22 percent in 1944, 25 percent in 1945, 26 percent in 1946, 28 percent in 1947, 26 percent in 1948, and 29 percent in 1949.

Lead content of lead and zinc pigments produced by domestic manufacturers, by sources, 1948–49, in short tons

Pigment	1948				1949

[1] These figures are higher than those shown in the report on Secondary Metals—Nonferrous because they include zinc recovered from byproduct sludges, residues, etc., not classified as purchased scrap material.
[2] Excludes zinc sulfide, data for which Bureau of Mines not at liberty to publish.

CONSUMPTION AND USES

LEAD PIGMENTS

White Lead.—A large part of the shipments of white lead reported was not classified as to destination; as a consequence, only 63 percent is shown as going to paint manufacturers. Doubtless the customary 90-plus percent actually was used to make paint in 1949. Shipments of white lead to makers of ceramics declined again in 1949 and were not much more than half of the tonnage for 1947.

Distribution of white lead (dry and in oil) shipments, by industries, 1940–44 (average) and 1945–49, in short tons

Industry	1940-44 (average) [1]	1945	1946 [2]	1947	1948	1949
Paints	79,406	46,418	60,943	61,265	40,892	17,350
Ceramics	2,187	839	1,367	1,665	1,369	894
Unclassified	6,226	3,913	4,191	5,857	3,809	9,111
Total	87,819	51,170	66,501	68,787	46,070	27,355

[1] Reported as sales.
[2] Data for basic lead sulfate included with white lead; Bureau of Mines not at liberty to show separately.

Basic Lead Sulfate.—A distribution of basic lead sulfate shipments by uses has not been available for publication since that for 1945, when 3,009 short tons went to the paint industry, 200 tons to the rubber industry, and 686 tons to other industries. Substantial quantities of lead sulfate are also used as an intermediate product in the manufacture of leaded zinc oxide. Such quantities have always been shown in this chapter series under leaded zinc oxide rather than basic lead sulfate.

Red Lead.—Storage batteries, regularly the principal use of red lead, took 49 percent of the total shipped in 1949 but dropped proportionately more than paints, second in importance. Ceramics, which

had been gaining, had the sharpest drop, falling to less than half of the 1948 tonnage.

According to a recent study [1] by the Battelle Memorial Institute for the American Iron and Steel Institute, red lead appears to be outstanding for enclosed structural members in steel-housing construction. Some 34 kinds of paint systems were studied during the test. In one phase of the testing, one painted panel was damaged by scratching it lengthwise through the paint film to base metal. In the case of damaged films exposed to immersion in water, "only System C (red lead) offered protection to the bare steel in the damaged zone. In fact, for the majority of the other systems, continued exposure would have resulted in actual perforation of the base metal in this area in a relatively short period of time."

Distribution of red-lead shipments, by industries, 1940–44 (average) and 1945–49, in short tons

Industry	1940–44 (average) [1]	1945	1946	1947	1948	1949
Storage batteries	26,899	26,725	19,115	20,883	14,854	12,163

Total	50,351	47,381	32,526	36,064	30,787	24,866

[1] Reported as sales.

Orange Mineral.—No shipments of orange mineral have been reported since 1946, when 78 short tons went to the ink industry, 18 tons to the color-pigment industry, and 27 tons to other industries.

Litharge.—Storage batteries took 64 percent of the litharge shipped in 1949 and 65 percent in 1948. Ceramics dropped proportionately more than other uses and accounted for 11 percent of the 1949 total, compared with 13 percent. The manufacture of chrome pigments was the only use that increased in 1949, rising 15 percent; this use took 7 percent of the total, compared with 5 percent in 1948. Chrome pigments had the sharpest percentage drop in 1948. Oil refining and

Distribution of litharge shipments, by industries, 1940–44 (average) and 1945–49, in short tons

[1] Pray, H. A., and Peoples, R. S., No. 31 of a series entitled "Contributions to the Metallurgy of Steel": Abs. in Am. Metal Market, vol. 54, No. 204, Oct. 21, 1949, p. 7.

insecticides maintained their same relative standings in 1949 as in 1948, taking 5 and 4 percent, respectively, of the total shipped. Varnish took 4 compared with 3 percent. Rubber manufacture and floor coverings had the greatest percentage drops, both falling to less than half of the 1948 quantities.

Lead Suboxide.—Storage-battery manufacturers themselves produce from pig lead a black suboxide of lead, which they use as a substitute for litharge. As previously noted, production in 1949 was 55,000 short tons, a fifth less than in the peak year 1947.

ZINC PIGMENTS AND SALTS

Zinc Oxide.—As usual, the manufacture of rubber took more than half of the zinc oxide shipped—53 percent in 1949 compared with 55 percent in 1948—indicating a slightly greater drop in the most important use than in the total distributed. The manufacture of paint decreased only 2 percent in 1949 and was less affected by the drop in zinc oxide shipments than any of the other uses. The use of zinc oxide for ceramics had established new peaks for 3 successive years ended in 1948. This use, coated fabrics and textiles, and floor coverings had declined considerably above that for total shipments, or 43, 45, and 46 percent, respectively.

Distribution of zinc oxide shipments, by industries, 1940–44 (average) and 1945–49, in short tons

Industry	1940–44 (average)[1]	1945	1946	1947	1948	1949

[1] Reported as sales.

Lithopone.—Paints, varnish, and lacquers regularly take close to three-quarters of the total lithopone sold. In 1949, 72 percent of shipments was for paints, etc., compared with 75 percent in 1948 and 82 percent in 1947. Paints, etc., took 46 percent less lithopone in 1949 than in 1948 and amounted to less than half of the totals for 1947 and 1946. Coated fabrics and textiles fell only 22 percent in 1949 and moved into second place as users of lithopone, replacing floor coverings, which dropped 49 percent. Consumption for rubber was 23 percent below 1948 but was higher than in every other year since 1941. The use of lithopone by paper makers rose from 3,086 tons in 1945 to 4,814 in 1948 but dropped to less than half of the latter quantity in 1949. Printing ink made the best showing of the uses of lithopone, with a drop of only 18 percent in 1949; 593 tons were shipped for this purpose compared with 727 in 1948, 720 in 1947, 830 in 1946, 864 in 1945, and 1,216 in 1944. One manufacturer regularly includes tonnages for ink as not separable from those sold for paint, but the foregoing tonnages compare totals for identical companies. Exports are included mainly with "Other," but at least one company classifies part of its exports according to end use.

Distribution of lithopone shipments, by industries, 1940–44 (average) and 1945–49, in short tons

Industry	1940–44 (average) [1]	1945	1946	1947	1948	1949

[1] Reported as sales.
[2] Includes a quantity, not separable, used for printing ink.

Zinc Chloride.—Statistics on the use and distribution of zinc chloride are not available. Studies of the effectiveness of zinc chloride and other chemicals in the treatment of mine timbers were summarized [2] recently. The report stated:

> In a service test of maple timbers treated by the hot- and cold-bath method and installed in main haulageways of the Athens mine of the Cleveland Cliffs Iron Co., Negaunee, Mich., zinc chloride-treated timbers had an average useful life of 13.3 years; borax-treated timbers, 11.2 years; and sodium-fluoride-treated timbers, 7.7 years. Untreated timbers used as controls had an average useful life of 3.8 years.
>
> Although it was intended in this experiment to compare the relative effectiveness of zinc chloride, borax, and sodium fluoride, the wide variations in absorptions and penetrations obtained with the three chemicals invalidate such comparison. The zinc chloride absorptions were about as desired, but the absorptions of borax and sodium fluoride (especially the latter) were too low. Although retention of these two chemicals was low, the timbers treated with them, as well as those treated with zinc chloride, proved to be longer-lived and more economical than the untreated timbers used in the test.

[2] Crawford, F. S., and Wirka, R. M., A Test of Treated Timbers in a Mine at Negaunee, Mich.: Bureau of Mines Rept. of Investigations 4622, 1950, 6 pp.

Research in connection with flame-proofing textiles was summarized[3] recently. The article gives an evaluation of several pigment-resin-type treated fabrics. One chemical combination used contained zinc chloride and another, zinc oxide.

Zinc Sulfate.—Rayon, the chief use for zinc sulfate in the past 3 years, established a new peak in 1949, rising 9 percent (dry basis) over the previous high in 1948. Shipments for agricultural purposes—the top use in 1946 when it was at a peak level—amounted to less than half of the quantity for rayon, having fallen 15 percent from 1948 and 56 percent from 1946. Chemicals and flotation reagents dropped 29 and 45 percent, respectively, the former having fallen even more sharply from tonnages for earlier years, whereas the latter compared favorably with years before 1948. However, the apparent decline in importance of zinc sulfate in chemicals may simply be a result of more precise data on shipments by uses. Contrary to the trend for most other uses, paints and varnish processing rose substantially in 1949. This use dropped notably in 1946; the 1949 increase marked resumption of the 1945 level of use.

PRICES

Total and average values received by producers for lead and zinc pigments and zinc salts are given in the tables in the first part of this report. Following two successive years (1947 and 1948) in which new peaks in average values for lead pigments were established, values dropped in 1949; the declines ranged from 16 percent for red lead and litharge to 3 percent for white lead (dry). Zinc average values likewise were at peaks for many years and in some instances perhaps for all time in the 2 years, but, except for leaded zinc oxide, were unlike those for lead pigments in 1949 and showed small gains. Total values of both types dropped substantially in 1949 owing chiefly to the smaller tonnages involved. The small gains in zinc-pigment average

[3] Church, James M., Little, Robt. W., and Coppick, Sydney, Evaluation of Flame-Resistant Fabrics; Ind. and Eng. Chem., vol. 42, No. 3, March 1950, pp. 418–427.

values probably indicate that sales during the year were greater at the higher part of the price range.

There were substantial drops in average quoted prices for lead pigments in 1949 from the all-time peaks established in 1948, and those for zinc pigments in general followed the same pattern. In most instances lead-pigment prices were at their lowest levels in June, made noteworthy recovery in the next several months, and returned to or close to midyear low points in December. Zinc-pigment quotations reached their lowest levels a little later in the year and after recoveries similar to those for the lead group resumed down trends but ended the year a little above the year's lowest figures.

Range of quotations on lead pigments and zinc pigments and salts at New York (or delivered in the East), 1946–49, in cents per pound

FOREIGN TRADE [1]

Imports of lead and zinc pigments are insignificant in relation to domestic shipments of the various items. Total value of lead-pigment entries, following a substantial percentage rise in 1948, dropped 77 percent in 1949 to close to the 1947 level. The declines were due to lower tonnages rather than to falling average values, despite the fact that prices were substantially lower at the end than at the beginning of the year. Imports of zinc pigments rose sharply in 1949 but were scarcely one-third of the total value of lead-pigments receipts.

The total value of exports of lead pigments gained and that of zinc pigments fell in 1949. Values of both classes were far in excess of corresponding imports but were small as compared with domestic shipments.

Values of both imports and exports of the lead and zinc compounds covered by the accompanying table dropped in 1949.

In quantity as well as value, exports of lithopone and of zinc oxide

[1] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

are the most important items in foreign trade in lead and zinc pigments and zinc salts. Both classes dropped in quantity and in value in 1949.

WORLD REVIEW

Canada.—A report of the Dominion Bureau of Statistics of Canada published early in 1950 gave data on pigments consumed by the paint and varnish industry in Canada in 1947 and 1948. The figures for 1948 are as follows (1947 figures for comparison in parentheses): Basic carbonate white lead (dry) 2,344 (3,264) short tons, basic carbonate white lead in oil 717 (1,741) tons, basic sulfate white lead 22 (7) tons, red lead including orange mineral 691 (625) tons, litharge 300 (312) tons, zinc oxide (lead-free) 2,975 (5,209) tons, leaded zinc oxide 2,096 (1,546) tons, lithopone (30 percent zinc sulfide) 11,851 (9,712) tons, titanium dioxide 5,766 (4,117) tons, extended titanium dioxide pigments 8,791 (7,199) tons, and "other white pigments" 590 (710) tons.

Canada's imports of lithopone, 14,787 and 12,736 tons, respectively, in 1948 and 1947, were large enough more than to cover use in the 2 years. Imports of zinc white (zinc oxide) were 1,732 and 2,205 tons, respectively. Imports of the other items given in the preceding paragraph are very small, although titanium pigments were not shown separately in the report. According to United States records for titanium dioxide and pigments, 19,787 tons were exported to Canada in 1948 and 13,274 tons in 1947.

Germany.—According to a recent article,[5] the prewar production of lithopone in all of Germany was about 100,000 tons, the greater part of the industry being located in what after the war was the British zone. The original capacity was said to be virtually intact, and maximum production could probably be obtained without much difficulty. Sales of lithopone in the American-British zones were said[6] to have decreased because of the slowing of building operations and a shortage of linseed oil. Exports, however, were said to be expanding, going largely to the Middle East, eastern Asia, the United Kingdom, and Scandinavia.

United Kingdom.—Construction of an additional unit to produce lithopone was reported[7] begun at the Widnes, Lancashire, England, plant of the Imperial Smelting Corp., Ltd.

Lime[1]

By G. W. Josephson and F. D. Gradijan

GENERAL SUMMARY

THE GENERAL decline in industrial activity in 1949, particularly in the early part of the year, was reflected in reduced output of lime. Sales totaled 6,318,302 short tons, 13 percent lower than the record tonnage of 1948. Of the total sales, 73 percent were in the form of quicklime and 27 percent hydrated. The average value of quicklime per ton increased from $9.96 in 1948 to $10.48 in 1949. Hydrated-lime values rose from $11.50 in 1948 to $12.31 in 1949. The total number of active plants was virtually the same as in the previous year.

Salient statistics of the open-market lime industry in the United States, 1925–29 (average), 1935–39 (average), and 1948–49

[1] Selling value, f. o. b. plant, excluding cost of containers.

As lime is an inexpensive commodity having wide utility, its sales are influenced by conditions in various consuming industries. Figure 1 shows the correlation between the use of open-market lime and trends in the construction industry compared with general industrial production.

Trends and sales of open-market lime sold for specified uses in the past 25 years are shown in figure 2. The trends of these curves are influenced not only by demands but also by the volume of captive lime production, the output of which is not shown in the figure.

[1] Figures in this chapter pertain to open-market lime and exclude coverage of most captive lime operations.

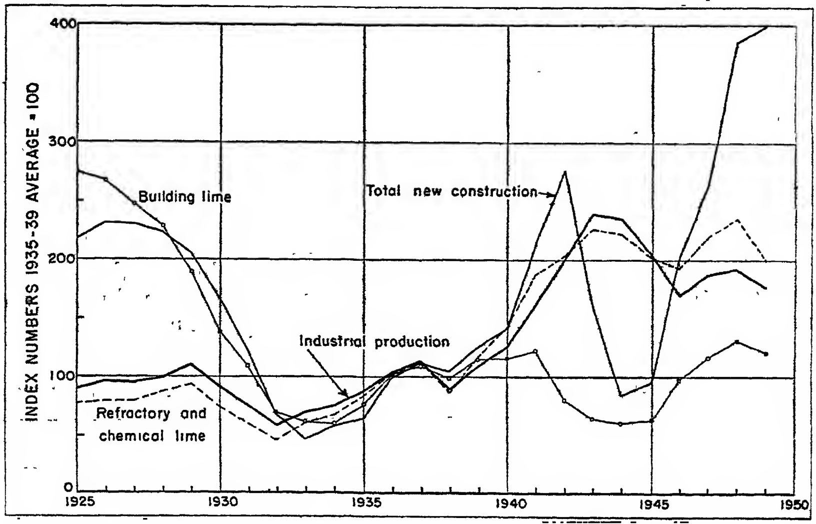

FIGURE 1.—Sales of refractory and building lime compared with total new construction and industrial production, 1925–49. Units are reduced to percentages of the 1935–39 average. Statistics on value of construction from the Bureau of Foreign and Domestic Commerce (Survey of Current Business, March 1950) and on industrial production from the Federal Reserve Board.

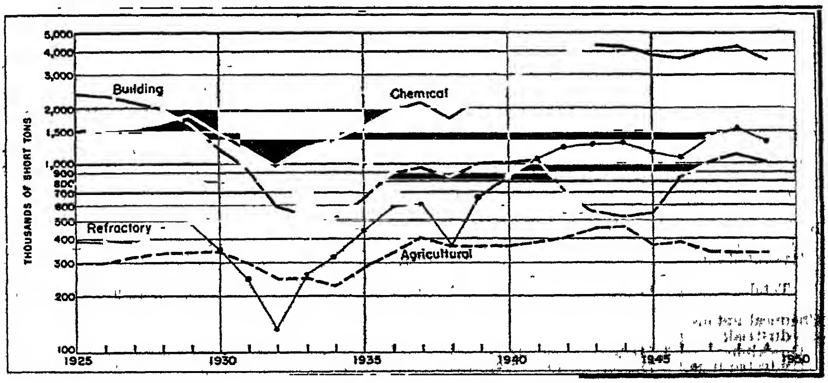

FIGURE 2.—Trends in major uses of lime, 1925–49.

DOMESTIC PRODUCTION

Total production of open-market lime (as indicated by sales) declined 13 percent in tonnage and 8 percent in value. The major declines were in refractory and in chemical and industrial lime. Both of these categories were down 15 percent. Building lime decreased 8 percent, and agricultural increased 2 percent. Stocks are said to be comparatively small and constant, so the sales statistics in this chapter are believed to be the equivalent of production of open-market lime.

Captive Tonnage.—In general, the lime statistics included in this chapter are limited to open-market lime, except that, in a few instances, a relatively small quantity of captive tonnage is included where it is particularly desirable to show complete figures for consumption by use. Specifically, in the statistics of lime sold or used in the United States in 1949, there was included a total of 355,367 short tons of captive tonnage, distributed as follows: 11,383 tons for building, 232,451 for metallurgical uses, 77,284 for miscellaneous chemical uses, and 34,249 tons of refractory lime. If it is desired to obtain a more comprehensive total for lime production, a figure of approximately the proper order of magnitude can be calculated from limestone tonnages (shown in the Stone chapter of this volume) consumed in the uses in which limestone is generally calcined.

Lime sold by producers in the United States, 1948–49, by types and major uses

	1948				1949

[1] Selling value, f. o. b. plant, excluding cost of container.
[2] Includes lime used by producers (captive tonnage) as follows—1948: 363,368 tons, valued at $2,843,972; 1949: 355,367 tons, $3,171,392.

Size of Plants.—In 1949 there were virtually the same number of open-market lime plants active in the United States as in 1948. Of the total 180 plants, the 38 having individual production rates greater than 50,000 tons per year contributed 71 percent of the total output.

Distribution of open-market lime (including refractory) plants, 1947–49, according to size of production

by Pennsylvania and Missouri in that order. These three States together contributed 55 percent of the United States output.

Hydrated Lime.—Most of the lime sold is in the form of quicklime, but substantial quantities are also sold in hydrated form. In 1949, 27 percent of the total lime output was sold as hydrated lime compared with 25 percent in 1948.

[1] Includes the following States and number of plants in 1949 (1948 same as 1949, unless shown differently in parentheses): Arizona 2, Arkansas 1, Colorado 1, Connecticut 1, Florida 1, Indiana 1, Maine 2, Michigan 1, Minnesota 1, Montana 1, Nevada 1, New Jersey 3, New York 2, Oklahoma 1, Puerto Rico 4 (3), South Dakota 0 (1), Utah 3 (2), Washington 1, and Wisconsin 6.

CONSUMPTION AND USES

The chemical and industrial uses of lime have attained great importance during recent years; but, in consonance with the moderate decline in industrial production in 1949, lime, for these uses, declined from the high level of 1948. Lime for water purification, which showed a gain of 5 percent, was the only important chemical or industrial use that increased in 1949. A small increase was recorded for agricultural lime, but building lime and that applied to refractory uses (dead-burned dolomite) experienced declines of 8 and 15 percent, respectively.

The following table of lime sales by States and uses provides geographic data that may be of interest. Although many figures are concealed to avoid revealing confidential information, the table shows, in general, the more important uses to which the lime of each State is applied and the relative importance of each State as a lime producer. The tables on sales of lime according to use indicate the great variety of uses to which lime is applied and its importance in agriculture, building construction, and industry in general.

Lime sold by producers in the United States in 1949, by States and uses

State or Territory	Agricultural		Building		Chemical and industrial										Refractory		Total

Total		10,155,280	35,810,268			10,431,800	37,295,894	

[1] Calculated upon basis of average percentages used by the National Lime Association, as follows: Quicklime (including lime from oystershells), 85 percent; hydrated lime, 70 percent; pulverized uncalcined limestone and oystershells, 47 percent; calcareous marl, 42 percent.

[2] Figures compiled by Fish and Wildlife Service.

Apparent Consumption.—Lime plants are widely distributed, and most of the lime manufactured is used in local market areas. However, as some States produce a surplus and others are deficient in production, considerable quantities enter interstate trade. Furthermore, limes vary considerably in physical and chemical properties, and the peculiar needs of various industries commonly demand shipments from distant points. The principal States that "export" lime beyond their borders are Ohio, Missouri, Pennsylvania, and West Virginia. Sales, shipments, and supplies of lime available for consumption in continental United States, by States, and groups of States are listed in the accompanying tables.

Apparent consumption of open-market lime in continental United States in 1949, by States, in short tons

PRICES

The uptrend in prices noted in 1948 continued in 1949. In the latter year the average selling price, f. o. b. plant, was $10.97 per short ton compared with $10.35 in 1948. The average selling price of quicklime in 1949 was $10.48 ($9.96 in 1948) and of hydrated lime $12.31 ($11.50 in 1948).

FOREIGN TRADE[2]

Imports.—Imports of lime into the United States are relatively small. Most of it enters from Canada to satisfy local needs in border areas, particularly in the State of Washington. Imports during recent years are indicated in the following tables.

Exports.—Exports of lime increased steadily during recent years but are still relatively small. Canada and Latin America are the principal foreign markets.

2 Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Lime imported for consumption in the United States, 1945–49

TECHNOLOGY

A kiln embodying the new "fluosolids" method of calcining limestone has been placed in operation at the plant of the New England Lime Co. at Adams, Mass. The new kiln will produce about half of the lime made at this plant. An encouraging decrease in production costs has been noted.

A new type of limekiln adapted to calcining small-size stone has been introduced in a lime plant at Seattle, Yorkshire, England. It is the second kiln of this type to be used. The first one is employed for calcining chalk into lime at Croydon, Surrey. The successful use of such a kiln where limestone is the raw material would be advantageous because, in many instances, the small sizes that inevitably accumulate

are wasted owing to the difficulty of calcining them in standard kilns. No data are now available on the design of the new kilns.

The Kelley Island Lime & Transport Co. has placed in operation at White Rock, Ohio, four forced-draft, center-burner gas kilns designed by Azbe Engineers, Inc. They are equipped with the most modern control instruments. High efficiency is reportedly attained. Each kiln produces 50 tons of lime a day and the fuel : lime ratio approaches 1 : 5.[3]

G. & W. H. Corson, Inc., Plymouth Meeting, Pa., has been perfecting for some years a process of pressure hydration of dolomitic (high-magnesium) lime. A product of superior quality has been produced. The method of manufacture has gradually evolved from batch to continuous process. The latest improvements are incorporated in a continuous hydrator built in 1948. An "explosion" method is employed to eliminate surplus water from the hydrate.

The National Lime Association is sponsoring at the Massachusetts Institute of Technology fundamental research devoted primarily to correlation of lime-burning conditions with the properties of lime. The rate of slaking, for instance, is influenced greatly by the time and temperature of calcination. Pure, optical-grade, cleavable calcite is used as a reference material. Effects of impurities will be a later project objective.[4]

Magnesium

By Richard H. Mote and Horace F. Kurtz

GENERAL SUMMARY

AN INCREASE in production and consumption of magnesium, as contrasted to most other metals, was recorded in 1949. Its unique economic position was emphasized by a stable market price, which remained unchanged throughout the year at 20.5 cents a pound for domestic virgin ingot, commercially pure. The total output of 11,598 short tons produced during 1949 came from the Dow Chemical Co. reduction plant at Freeport, Tex. The privately owned capacity of this plant was increased in 1949 through acquisition of the Government-held portion of the facility. Wider acceptance of magnesium for structural products was indicated by the 1949 data on consumption, although much of the metal was used for military purposes. Apparent consumption of primary magnesium totaled 12,545 tons compared with 8,215 tons in 1948. In addition to primary supplies, about 6,000 tons of magnesium were recovered from secondary sources. Year-end stocks of primary metal at the only producing plant and at consumers' plants were approximately equal to 1 year's production at the average rate of output in 1948–49.

Salient statistics of the magnesium metal industry in the United States, 1940–44 (average) and 1945–49

	1940–44 (average)	1945	1946	1947	1948	1949
Production of primary magnesium [1] ... short tons	82,441	32,792	5,317	12,344	10,003	11,598
Quoted price per pound ... cents	22.6	20.5	20.5	20.5	20.5	20.5
Consumption, apparent ... short tons	72,947	43,000	8,709	4,949	8,215	12,545
Exports [2] ... do	12,617	518	207	315	274	432
World production ... do	143,300	54,900	12,900	[3] 21,400	[3] 21,300	23,700

[1] Ingot equivalent.
[2] Magnesium metal and alloys, 1940 and 1943–45; metal, 1941–42, and 1946–49.
[3] Revised figure.

United States conducted little foreign trade in magnesium during 1949, although imports of metal, including scrap, increased to 2,560 tons. World production of magnesium was estimated to have gained 11 percent, totaling 21,500 short tons. United States produced nearly half of the total, and United Kingdom, U. S. S. R., and France, most of the remainder.

PRODUCTION

Primary.—Since July 1946 the Freeport, Tex., plant of the Dow Chemical Co. has been the only domestic producer of primary magnesium. Output remained nearly constant throughout 1949 and totaled 11,598 short tons, or 16 percent above the 1948 figure. Although production has been only a small fraction of the record achieved during World War II, it has been maintained considerably above prewar levels and has gradually increased since the summer of 1948.

Increased demand for magnesium encouraged the Dow Chemical Co. to expedite the anticipated purchase of the Government facilities at Freeport, Tex., in 1949. Dow thereby increased the rated annual capacity of its plant to 18,000 short tons, although production rates in excess of this capacity had previously been attained. Sale of the Government-owned portion of the plant was announced by the Federal Works Agency in May 1949. In addition to this privately owned plant, the Government had seven plants remaining from World War II which have been placed in stand-by condition for emergency use. Two of these plants are electrolytic reduction plants located at Valasco, Tex., and Painesville, Ohio, and five are ferrosilicon reduction plants at Luckey, Ohio; Canaan, Conn.; Manteca, Calif.; Wingdale, N. Y.; and Spokane, Wash.

Production of primary magnesium in the United States, 1948–49, by months, in short tons [1]

Month	1948	1949	Month	1948	1949
January	883	988	August	809	970
February	830	884	September	819	974
March	887	988	October	873	941
April	801	958	November	814	969
May	797	987	December	932	1,004
June	766	950			
July	792	985	Total	10,003	11,598

[1] Monthly figures have been adjusted to final annual totals.

Although magnesium was considered an important war material by Government military authorities, the supply of raw materials for producing the metal has never been critical. The only commercial producer in 1949 used sea water as its source. It has been estimated that a cubic mile of ocean water contains 6,000,000 tons of magnesium—far more than the world output since the metal was first produced. Dolomite, magnesite, underground brines, and various other magnesium-bearing materials also provide virtually inexhaustible supplies of ore suitable for other production methods.[1]

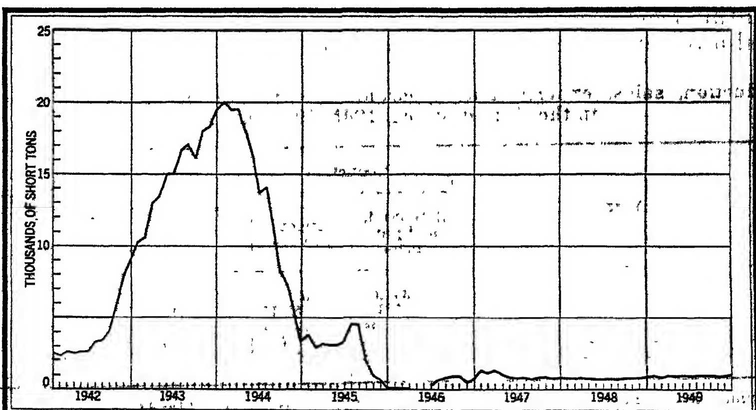

FIGURE 1.—Trends in domestic production of primary magnesium, 1942–49.

[1] Gross, W. H., The Story of Magnesium: Am. Soc. for Metals, Cleveland, Ohio, 1949, 258 pp.

Magnesium fabricating facilities were more active during 1949 as a result of increased demand for sheet, extrusions, and castings. Expansion of rolling-mill capacity was indicated by plans revealed in 1949.

Secondary.—Recovery of secondary magnesium, including alloying ingredients and secondary magnesium incorporated in primary ingot, totaled 5,962 short tons in 1949 compared with 7,553 tons (revised) in 1948. Of this quantity, 5,860 tons were recovered from 6,458 tons of magnesium-base scrap in 1949. Old scrap constituted about 48 percent of the scrap consumed compared with 52 percent (revised) in 1948. Of the 1949 recovery, 4,249 tons were in ingot form, 681 tons in castings, 96 tons in magnesium-alloy shapes, 294 tons in aluminum-base alloys, 4 tons in zinc-base alloys, 555 tons in anodes and strip for cathodic protection, and 83 tons in chemicals and other nonrecoverable forms. Additional information on secondary magnesium may be found in the Secondary Metals—Nonferrous chapter of this volume.

CONSUMPTION AND USES

Emerging from a postwar recession in the use of magnesium, which was at its lowest in 1947 and early 1948, shipments of primary metal from the only producing plant increased 53 percent to 12,545 short tons in 1949. Demand for defense purposes brought sales to a high level during 1949 despite a decline in most other industries. Use of metal for military aircraft, which during World War II caused the first great advances in the application of magnesium, was responsible for renewed gains in consumption. Increasing realization of the advantages in the weight factor of magnesium over aluminum castings for aircraft resulted in gains in this field, and demand for sheet and extrusions was also strong. Magnesium was utilized too in the production of movable civilian products such as tools, handling equipment, machinery and vehicle parts, and other products where light weight resulted in savings in operation costs.

Consumers reported greater use of primary magnesium during 1949, resulting from a nearly 50-percent increase in its application for structural products. Largest advances were noted in consumption for sand

Production, sales, exports, and apparent consumption of primary magnesium in the United States, 1945–49, in short tons

Year	Production		Sales	Exports [1]	Apparent consumption [2]
	Raw, crude, and pure ingot	Ingot equivalent			
1945	33,106	32,792	3,496	496	43,000
1946	5,317	5,317	8,916	207	8,709
1947	12,344	12,344	5,264	315	4,949
1948	10,003	10,003	8,489	274	8,215
1949	11,598	11,598	12,977	432	12,545

[1] Primary metal only. Alloy exports in addition: 22 tons in 1945; none in 1946–49.
[2] Does not consider fluctuations in consumers' stocks and metal derived from scrap. Withdrawals from producers' stocks totaled 18,704 tons in 1945, 3,500 in 1946, and 1,379 in 1949. Additions to producers' stocks totaled 7,060 tons in 1947 and 1,514 tons in 1948.

castings, sheet, and extrusions. Extrusions continued to lead the field of uses, but sand castings replaced aluminum-base alloys as the second largest classification. Less primary magnesium was used in nonstructural products than in 1948.

The Bureau of Census, United States Department of Commerce, reported that shipments of magnesium castings and wrought products increased 14 and 41 percent, respectively, in 1949.

Use of magnesium in cathodic protection of steel pipelines, water heaters, and surfaces exposed to sea water continued to increase. Because of its position in the electrochemical series, magnesium can act as an anode in electrolytic action and greatly reduce corrosion of other metals. For this expendable use magnesium frequently is derived from scrap metal. During 1949 magnesium also was used in increasing quantities for photoengravings and blocking bases in the printing industry. Comparing favorably with other photoengraving metals, particularly zinc, magnesium afforded fine-grained etchings at high speeds, with less acid in the baths. The magnesium plates were long-wearing while light in weight for easy handling.

Transportation remained the largest field of magnesium consumption during 1949. Over 5 tons of magnesium sheet was used in the production of each B–36 airplane, over 1 ton in the airframe of the Navy's Chance-Vought F7U, and approximately 1 ton of extrusions in the floor beams of the Douglas C–124 Globemaster. Substantial quantities of magnesium were used in commercial highway vehicles, especially for extruded truck flooring.

Actual domestic consumption of primary magnesium (ingot equivalent and magnesium content of magnesium-base alloys) by uses, 1945–49, in short tons

Product	1945 [1]	1946	1947	1948	1949

[2] Revised figure.
[3] Less than 1 ton.
[4] Includes primary metal consumed in making secondary alloy.

Numerous new tools for construction work were designed in 1949 to utilize magnesium's light weight and high strength. Demand for faster and more efficient textile equipment [2] encouraged the use of magnesium for manufacturing machinery.

Other new uses for magnesium included wall forms for pouring concrete and new die castings for automobiles. Consumption of magnesium in the production of titanium metal appeared to be another potentially large use developed since World War II. Research was in progress during 1949 to determine the possibility of using magnesium powder as a jet-engine fuel.

STOCKS

Inventories of primary magnesium ingot at the Freeport, Tex., plant declined to approximately two-thirds of annual production by December 31, 1949. Total consumers' stocks of primary metal comprised about 2,500 tons, virtually the same as at the end of 1948.

Government agencies continued to hold the large quantities of magnesium mentioned in the 1948 edition of this series. Of the approximately 25,000 tons of low-zinc magnesium alloy bomb bodies reported in plants throughout the United States, an undisclosed portion was demilitarized and transferred to the Bureau of Federal Supply. Magnesium was not on the list of materials to be purchased for the National Stockpile in 1949. Storage of magnesium ingots in a manner that would prevent deterioration continued to be a stockpiling problem.

PRICES

For the seventh consecutive year the base price of standard virgin magnesium ingot remained at 20.5 cents per pound, the price established in January 1943. The stability of primary magnesium prices and the reductions made in certain manufacturing processes have been one of the major selling points for the metal during the postwar period.

FOREIGN TRADE [3]

Imports.—During 1949 imports of magnesium in all forms increased 278 percent to a record level of 2,560 short tons. Virtually all the receipts were classified as metallic and scrap; the total consisted of 962 tons from United Kingdom, 564 tons from Germany, 421 tons from Austria, 212 tons from Czechoslovakia, 194 tons from Switzerland, 99 tons from Italy, 38 tons from Egypt, 30 tons from France, 28 tons from Belgium, 7 tons from Sweden, and 5 tons from Canada. Effective tariff rates on magnesium in 1949 were as follows: Metallic, 20 cents per pound; metallic scrap, 20 cents per pound (duty suspended until June 30, 1949, but suspension discontinued thereafter); and alloys, powder, sheets, tubing, wire, manufactures, etc., 20 cents per pound on magnesium content plus 10 percent ad valorem.

Exports.—Magnesium exports totaled 59 percent above the 444 tons shipped in 1948. Of the metal exported in primary form during 1949, 360 tons went to Mexico, 27 tons to Argentina, 20 tons to Colombia, and the remaining 25 tons to 9 other countries. Venezuela

TECHNOLOGY

Magnesium has long been known to have the unique qualities of light weight coupled with high strength, good workability at comparatively low temperatures, and excellent machinability. Only in the last decade, however, have many of the best alloys been developed. During this period industry has become more familiar with the characteristics of this metal. The fear of igniting magnesium, prevalent before World War II, has been greatly reduced by improved handling techniques.

Like most other metals, pure magnesium is rarely used for structural purposes. Aluminum, zinc, manganese, zirconium, and rare earths have been among the most common alloying ingredients. The recent development of jet engines has increased the need for magnesium alloys capable of high-temperature operation. Two new alloys, a magnesium-cerium-zirconium casting alloy for elevated temperature applications and a magnesium-zinc-zirconium alloy for high-strength extrusions, were introduced in 1949. A comprehensive survey[4] of magnesium alloys revealed that the zinc-silver-manganese-calcium system had good potentialities for magnesium-base alloys. Additional experience in using small quantities of magnesium to increase ductility and strength of cast iron was gained during 1949.

In keeping with the growing knowledge of production technology, much information on designing, casting,[5] extruding, rolling, joining, and surface-treating magnesium has been published since World War II. In 1949, electroplating magnesium to provide finishes for a variety of uses became a commercial practice.

WORLD REVIEW

World production of primary magnesium in 1949 was estimated at 21,500 metric tons or about 11 percent above the 1948 total. Most of the increase was attributed to larger outputs in the United States and United Kingdom. No appreciable gain in civilian demand was noted during the year, and, to a large extent, world markets continued to rely upon military consumption.

[1] Data not available; estimate by author of chapter included in total.
[2] Estimated figure.
[3] January-February only. Planned production for March, 2,830 tons.
[4] British and American zones only.
[5] Includes secondary metal.

Canada.—There was no magnesium production in 1949 from the ferrosilicon plant of Dominion Magnesium, Ltd., at Haley, Ont. The company has utilized stocks of magnesium accumulated during the war years to supply its markets in lieu of output from the plant, which has not produced magnesium since 1945. During the latter part of 1949 the company was considering resuming magnesium production to replenish its inventories. The Aluminium Co. of Canada temporarily discontinued production of magnesium in 1949.

Germany.—Of the five magnesium reduction plants that operated in Germany during the war, four were I. G. Farben-industrie establishments located in what is now the Soviet Zone. It was reported [6] in November that all magnesium productive capacity in the Soviet Zone had been dismantled except the electrolytic plant at Bitterfeld, which was retained for the production of calcium metal.

The American authorities in Western Germany were reported [7] to have ordered during the latter part of 1949 the dismantling of the idle Wintershall magnesium plant at Heringen.

United Kingdom.—During 1949 magnesium fabricators in the United Kingdom produced 732 long tons of sheet and strip, 56 tons of extrusions, and 2,748 tons of castings other than bombs.

Magnesium Compounds

By Joseph C. Arundale and F. M. Barsigian

GENERAL SUMMARY

MAGNESITE production in 1949 was the lowest in a decade. Sales of magnesias, particularly refractory magnesias, used principally by the steel industry, were affected by the severe curtailment of steel production to which strikes in the coal industry, a serious strike in the steel industry itself, and the general business recession were contributory factors. Lower consumption, partial liquidation of consumer inventories, and a cautious buyers' market combined to restrict sales of most other magnesias and magnesium compounds.

Salient statistics of magnesite, magnesia, and dead-burned dolomite in the United States, 1945–49

[3] Average receipts f. o. b. mine shipping point.

DOMESTIC PRODUCTION

Magnesite.—Production of magnesite in 1949 was the lowest since 1939. The tonnage of refractory grades of magnesia sold or used by producers in 1949 dropped sharply, owing principally to curtailment of steel production during the year. Sales of caustic-calcined were less affected but were lower than in the previous year.

Magnesia sold or used by producers in the United States, 1948–49, by kinds and sources

Magnesia	From magnesite, brucite, and dolomite[1]		From well brines, raw sea water, and sea-water bitterns[1]		Total

[1] Magnesia made from a combination of dolomite and sea water is included with that from sea water.

Dolomite.—Reduction in the output of steel also was reflected in the decreased sales of dead-burned dolomite, which were the lowest since 1946.

The manufacture of refractory dolomite, including raw material requirements, processing, and costs, was discussed in an article.[1]

Additional information on dolomite may be found in the Stone and Lime chapters of this volume.

Dead-burned dolomite sold in and imported into the United States, 1945–49

[1] Reported as "Dead-burned basic refractory material."
[2] Less than 1 ton.

Other Magnesium Compounds.—Production and sales of both light and heavy high-grade magnesias and magnesium carbonate in 1949 followed the general trend and were lower as a result of the moderate recession in consuming industries.

Precipitated magnesium carbonate	11	60,898	7,315	939,306	52,798
1949					
Specified magnesias (basis 100 percent MgO), U. S. P. and technical:					
Extra-light and light	5	1,637	1,644	837,751	
Heavy	3	933	949	395,994	(3)
Total	[4] 5		2,593	1,233,745	(3)
Precipitated magnesium carbonate	10	55,925	7,273	924,299	48,641

[1] In addition, in 1948–49, magnesium chloride, hydroxide, nitrate, and sulfate were produced. Bureau of Mines not at liberty to publish figures.
[2] Sales by a producer to an affiliated consumer for immediate use are not included with "Sold" but are with "Used."
[3] Bureau of Mines not at liberty to publish figure.
[4] A plant producing more than 1 grade is counted but once in arriving at total.

REVIEW BY STATES

California.—Johns-Manville Products Corp., 22 East Fortieth Street, New York 16, N. Y., produced magnesium carbonate from purchased magnesium hydroxide at Redwood City, Calif., for use in 85-percent magnesia insulation. Kaiser Aluminum & Chemical Corp. (formerly Permanente Metals Corp.), Kaiser Building, Oakland, Calif., operated its magnesia-from-sea-water plant at Moss Landing, producing refractory and caustic-calcined magnesias. Marine Magnesium Products Corp., South San Francisco, Calif., recovered precipitated magnesium carbonate, magnesium hydroxide, and specialty magnesias, using lime, dolomite, and water from San Francisco Bay as raw materials. The Paraffine Companies, Inc., 1550 Powell Street, Emeryville 8, Calif., produced magnesium carbonate from purchased magnesium hydroxide for use in 85-percent magnesia insulation. This plant was closed for 3½ months owing to a strike. Westvaco Chemical Division, Food Machinery & Chemical Corp., 405 Lexington Avenue, New York 17, N. Y., produced a small quantity of magnesite from its western mine near Livermore, Calif., and reported that its calcining plant was idle during 1949. This firm also produced at its Newark plant refractory and caustic-calcined magnesia from sea-water bitterns and dolomite and caustic-calcined magnesia from magnesite. At its Chula Vista plant it recovered magnesium chloride from sea-water bitterns.

Illinois.—Johns-Manville Corp., 22 East Fortieth Street, New York 16, N. Y., produced precipitated magnesium carbonate by the Pattinson process at its Waukegan, Ill., plant for use in 85-percent magnesia insulation.

Michigan.—The Dow Chemical Co., Midland, Mich., produced magnesium chloride and epsom salts from well brines, dolomite, and lime. Michigan Chemical Corp., St. Louis, Mich., produced magnesium carbonate, hydroxide, and magnesia from well brines, dolomite, and lime. The Morton Salt Co., 120 South LaSalle Street, Chicago 4, Ill., produced precipitated magnesium carbonate from well brines at its Manistee, Mich., plant. Standard Lime & Stone Co., 2000 First National Bank Building, Baltimore 3, Md., at its plant at Manistee, produced refractory-grade magnesia from well brines and lime.

Nevada.—Basic Refractories, Inc., 845 Hanna Building, Cleveland, Ohio, during 1949 announced purchase from the General Services Administration, Real Property Disposal Division (formerly War Assets Administration), of a large magnesite deposit in the Paradise Mountains, Nye County, Nev., together with an adjacent ore dressing and calcining plant.[2] This company, which is also the sole producer of brucite in the United States, continued to produce this material from its quarry at Gabbs, Nev.,[3] and shipped most of it to its plant at Maple Grove, Ohio, where it is processed into a line of refractories.

Sierra Magnesite Co., Box 8–A, Newark, Calif., mined magnesite at Gabbs for caustic-calcined use.

Standard Slag Co., Youngstown, Ohio, mined and shipped crude magnesite from its property in the Gabbs District. This company was reported to be installing facilities for calcining its product.[4]

New Jersey.—The J. T. Baker Chemical Co., Phillipsburg, N. J., produced magnesia and magnesium chloride and nitrate from purchased magnesium carbonate. Johns-Manville Corp., at its Manville plant, produced precipitated magnesium carbonate by the Pattinson process for use in 85-percent magnesia insulation. Northwest Magnesite Co., 1922 Farmers Bank Building, Pittsburgh 22, Pa., recovered refractory-grade magnesia from sea water and dolomite at its Cape May, N. J., plant.

Ohio.—The Diamond Alkali Co., 300 Union Commerce Building, Cleveland, Ohio, produced refractory magnesia from dolomite at Fairport.

Pennsylvania.—Both the Philip Carey Manufacturing Co., Cincinnati 15, Ohio, plant at Plymouth Meeting, Pa., and Keasbey & Mattison Co., Ambler, Pa., produced magnesia and precipitated magnesium carbonate. Ehret Magnesia Manufacturing Co., Valley Forge, Pa., produced precipitated magnesium carbonate. All three firms used the Pattinson process, and the magnesium carbonate was for use in 85-percent magnesia insulation.

Texas.—The Dow Chemical Co., at Freeport, Tex., recovered magnesium chloride from sea water as an intermediate in the production of magnesium metal. It also produced some magnesia. Texas

[4] Mining World, vol. 11, No. 9, August 1949, p. 73.

Industrial Minerals Corp., P. O. Box 25, Llano, Tex., produced magnesite in the last quarter of 1949.

Washington.—Laucks Chemical Co., 1008 Western Avenue, Seattle 4, Wash., mined epsomite and produced epsom salt at Tonasket. Northwest Magnesite Co., 1922 Farmers Bank Building, Pittsburgh 22, Pa., the largest magnesite producer in the United States, produced refractory magnesite near Chewelah. A fire at this company's Keystone quarry caused a temporary shutdown for repairs in the first part of the year, and on October 24 the company stopped all operations for the duration of the steel strike.[5]

West Virginia.—The Standard Lime & Stone Co. recovered refractory magnesia by leaching calcined dolomite at its Millville, W. Va., plant.

PRICES

According to E&MJ Metal and Mineral Markets, at the end of 1949 the price of dead-burned grain magnesite, per ton, in bulk, f. o. b. Chewelah, Wash., was quoted at $30.50 to $31; in bags, $35 to $35.50. The Westvaco Chemical Division of Food Machinery & Chemical Corp., reported no change in prices of its magnesias, which were quoted (carlots, f. o. b. California) as follows: Bulk and powdered caustic-calcined magnesite, $64 in bulk and $70 powdered in bags. The price of calcined sea-water magnesia remained at $64 per ton in bags, powdered. Kiln-run 90-percent sea-water periclase was quoted at $50.50 per ton.

According to the Oil, Paint and Drug Reporter, magnesium hydroxide, medicinal grade, was quoted at 29 to 30 cents per pound in 1949 as for the past few years; magnesium carbonate, technical grade, bags, carlots, freight equalized, was quoted at 9 cents per pound, and magnesium carbonate, U. S. P. grade, at 10¾ cents per pound. Magnesium carbonate is quoted freight allowed to New Jersey (except to Atlantic, Burlington, Cape May, Cumberland, Gloucester, Ocean, and Salem Counties) and to Philadelphia County, Pa. Freight was equalized with New York City on all other destinations. Magnesium chloride, flake, barrels, carlots, works, was quoted at $40 per ton. Epsom salts, technical, bags, carlots, was reduced to $2.15 per 100 pounds from $2.30 in 1948. Magnesia, calcined, technical, cartons, works, was quoted at 32 cents per pound at the end of the year; synthetic, rubber grade, cartons, works, was quoted at 29 to 31 cents per pound; U. S. P. light, cartons, at 34 cents per pound; heavy, barrels, at 36 cents per pound.

FOREIGN TRADE[6]

No imports of crude magnesite were reported during 1949, and imports of magnesias and other magnesium compounds were small. Rapid development of the domestic industry has given the United States a high degree of self-sufficiency in these materials.

[2] 20 pounds. [3] 198 pounds. [4] 138 pounds. [5] 50 pounds.

TECHNOLOGY

There were reports of a promising new catalyst for use in fluid catalyst cracking. This material is synthetic silica-magnesia. Test results indicate it to be superior to silica-alumina and treated natural clay with respect to gasoline yield and activity maintenance. Gasoline octane numbers, however, are lower than those obtained with silica-alumina. Results of pilot plant testing were summarized.[7]

The composition, expansion characteristics, properties, and quality control of refractory linings in induction furnace steel making were discussed in an article.[8]

The addition of volatilized silica to Sorel cement to improve the strength, volume stability, and resistance to moisture was the subject of a patent.[9]

A refractories handbook describes the forms of refractories and their uses, how they are made and the types available, properties of refractories and the construction of furnaces, and technical data.[10]

A comprehensive article on the production of sea-water magnesia was published.[11]

WORLD REVIEW

Austria.—The United States Element of the Allied Commission for Austria presented a study of the rehabilitation of Austria, which contains a description of the economic development of Austria and a detailed discussion of the mining industry.[12]

The following magnesite operations were reported to be active in the latter part of 1949: Gr. Veitsch-Styria, Trieben-Styria, Breitenau-Styria, Kraubath-Styria, Oberdorf-Styria, Radenthein-Carinthia, Leogang-Land-Salzburg, Mayrhofen-Tyrol, and Fieberbrunn-Tyrol.[13]

Canada.—During the past 10 years Canada has expanded production of basic refractories sufficiently to supply its own needs and a surplus for exports. Dolomite and brucite are the raw materials of these refractories. A plant at Wakefield, Quebec, began production of magnesia from brucite in 1942. Products of this plant also are used for making magnesium metal at Arvid, and for agricultural and chemical purposes.[14]

[1] Unless otherwise stated, quantities in this table represent crude magnesite mined. In addition to countries listed, magnesite is also produced in Anglo-Egyptian Sudan, Canada, China, Cuba, U. S. S. R., and Yugoslavia, but data on tonnage of output are not available; estimates by senior author of chapter included in total.

The Canadian production was actually magnesitic dolomite and brucite, valued as follows: 1943: C$1,260,056; 1944: C$1,139,281; 1945: C$1,278,596; 1946: C$1,225,593; 1947: C$1,167,584; 1948: C$1,587,709.

[2] Data not available; estimate by senior author of chapter included in total.

[3] Estimate.

[4] January to June, inclusive.

[5] Exports.

[6] Bureau of Mines not at liberty to publish figure; included in total.

Greece.—Bandit activity on the Islands of Mytilini and Euboea were still hampering mining activity, although the security situation on Mytilini improved somewhat during 1949. An industrial loan for rehabilitating the Lesbos mine (Mytilini) was approved by the Central Loan Committee and was to provide for light mining equipment and construction of suitable loading facilities at the coast. The competitive position of Greece in relation to Yugoslavia and Turkey, two other magnesite producers, was summarized.[15]

Magnesite prospects near the airport of Salonika were reopened and a production of 25 to 30 tons daily was reported.[16]

India.—According to the Government of India, Japan has agreed to buy a substantial tonnage of magnesite from India under the trade agreement concluded between India and SCAP in Japan in 1948.[17]

Norway.—Construction was expected to begin late in 1949 on a magnesia plant at Norway's Heroya Kjemiske Fabried.[18]

Southern Rhodesia.—The discovery of an extensive deposit of magnesite northeast of Beitbridge, Southern Rhodesia,[19] was reported.

Manganese

By Norwood B. Melcher

GENERAL SUMMARY

EVENTS affecting supplies of manganese ore for United States use in 1949 were overshadowed by the loss of Russia as the principal supplier. Late in 1948 Russian suppliers notified importers in the United States that future shipments would be reduced to token quantities. As a consequence, imports from Russia—which totaled 427,229 net tons or one-third of total receipts in 1948—dropped to 81,459 tons in 1949. Domestic consuming industry as well as the United States Government turned attention to other world sources to provide adequate tonnages for current consumption as well as stock piling. Government efforts were coordinated through a high-level interagency group known as the Interdepartmental Manganese Coordination Committee. James Boyd, Director of the Bureau of Mines, was named chairman of the committee, and a world-wide program was inaugurated to increase the supplies of this highly strategic commodity. As a result of cooperative efforts of industry and Government, the loss of the Russian supply was not only replaced from other sources, but total imports in 1949 of all grades increased 23 percent over 1948. Virtually all of these added imports were necessarily obtained by expansion in currently producing areas, and much of the increased tonnage was obtained from Gold Coast, India, and the Union of South Africa. Other sources increased their shipments wherever possible; and, with reduced United States consumption in 1949, industry was able to increase its inventories substantially. In spite of this progress in 1949 in the supply position, the important requirements for stock piling lagged, and the market remained strong at the close of the year. Consequently, efforts to expand existing sources still further and to speed new developments were intensified. It is not expected that any important new sources will reach full production in 1950, but increases in both Indian and South African shipments were anticipated for this year.

Salient statistics of the manganese industry in the United States, 1945–49, gross weight in short tons

	1945	1946	1947	1948	1949
Manganese ore (35 percent or more Mn):

Exports	2,393	7,513	305	51	----------
Consumption	148,037	112,700	120,019	102,392	75,841

[1] A small quantity of miscellaneous ore is included with battery ore.

India is the greatest potential source of manganese ore, except Russia, with its vast reserves of metallurgical-grade ore. From a standpoint of reserves, India probably could increase its exports to 1,000,000 tons annually, but serious transportation limitations would have to be overcome. The Gold Coast raised its exports to the United States from 132,681 tons in 1948 to 371,314 tons (including 55,832 tons of battery-grade ore) in 1949; this was an increase of 180 percent, but further expansion of this source is not considered feasible. Imports of ferromanganese made principally from Gold Coast ore decreased from 98,220 tons in 1948 to 65,014 tons in 1949. In terms of manganese ore, this is equivalent to a loss of 66,000 tons, which may have made possible, in part, the increase in imports of ore from that country. The Union of South Africa is capable of further expansion as a source of manganese ore; United States imports increased from 216,575 tons in 1948 to 354,265 tons in 1949, an increase of 64 percent. It is expected that imports will be increased further in 1950 to more than 500,000 tons as a result of increased railroad-car capacity supplied for this purpose during late 1948 and early 1949. On the other hand, South African manganese ore, while of metallurgical grade, requires blending with other ores to make a suitable feed for ferromanganese blast furnaces. Much of this ore averages 40 percent Mn content, with high iron. Brazil increased its exports from existing manganese mines 5 percent above the 1948 total, while work progressed in the development of the Amapa and Morro do Urucum deposits. Small shipments were scheduled for 1950 from Urucum, but transportation difficulties are still a major problem. In the Territory of Amapa, development is under way, and plans are being expedited for the construction of transportation facilities from the manganese deposits to the Amazon River port of Macapa. No accurate estimate can yet be made as to when large production from the new mines can be realized. The Belgian Congo has substantial reserves of manganese ore, as yet undeveloped, in the upper Lulua River Valley. Negotiations are under way for mining these ores, and the future probably will see substantial production in this area.

Manganese mines in the United States produced 4 percent less ore in 1949 than in 1948. A trend toward a greater percentage of battery-grade material continued, with 14,983 short tons shipped in 1949 compared with 10,845 tons in 1948. Montana continued to be the principal producing State; however, numerous small operators in nine other States shipped small lots of high- and low-grade ores. The Bureau of Mines expanded its technical research for improved methods of beneficiating low-grade ores and recovering manganese from steel-plant wastes.

The total value of manganese ore produced in the United States advanced approximately 18 percent during 1949. The import duty remained unchanged at one-fourth cent per pound of contained manganese.

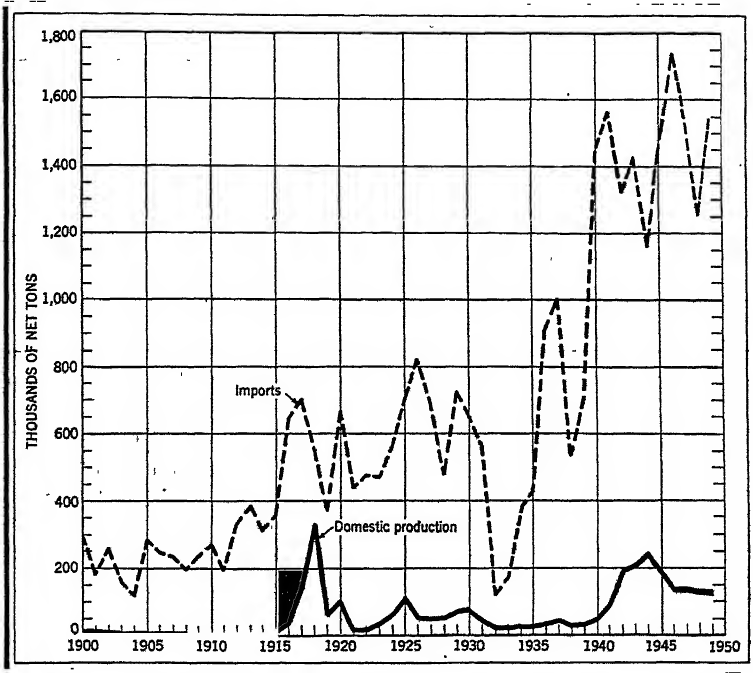

FIGURE 1.—General imports and domestic production (mine shipments) of manganese ore, 1900–1949.

DOMESTIC PRODUCTION

The following table shows the various types of manganiferous materials shipped by domestic producers from 1945 to 1949:

Manganiferous raw materials shipped by producers in the United States, 1945–49, in short tons

Year	Metallurgical ore				Battery ore (25 percent or more Mn)	Miscellaneous ore	
	Manganese ore (35 percent or more Mn)	Ferruginous manganese ore (10 to 35 percent Mn)	Manganiferous iron ore (5 to 10 percent Mn)	Manganiferous zinc residuum		35 percent or more Mn	10 to 35 percent Mn
1945	174,295	114,327	1,408,527	224,331	8,042	----------	----------
1946	134,381	100,402	1,070,694	205,786	[1] 8,295	[1] 959	87
1947	125,428	128,562	1,044,961	227,547	6,189	10	832
1948	119,828	139,580	1,198,523	291,383	10,845	427	2,462
1949	110,928	24,885	1,052,231	158,902	14,983	224	1,279

[1] A small quantity of miscellaneous ore is included with battery ore.

Shipments of various grades of manganese-bearing ores during the last 5 years are given by States in the accompanying tables. In addition, battery and miscellaneous ores were produced in Montana and Virginia, and manganiferous zinc residuum was produced from New Jersey zinc ores.

Metallurgical manganese ore shipped from mines in the United States, 1945–49, by States, in short tons

State	1945	1946	1947	1948	1949	State	1945	1946	1947	1948	1949

Total	1,408,527	1,070,694	1,044,961	1,198,523	1,052,231

Arizona.—The Denison Manganese Co. shipped manganese ore containing (natural) 47 percent Mn from the Long Valley and Heber mines in Coconino County, Ariz.

Arkansas.—The Denison Manganese Co. and the Standard Ore & Alloys Co. shipped manganese ore containing (natural) over 45 percent Mn, and ferruginous manganese ore containing (natural) less than 35 percent Mn, from various mines in the Batesville-Cushman district, Ark.

California.—From Plumas County, Calif., the Utah Construction Co. and Western Manganese mines shipped manganese ore containing (natural) 40 percent Mn, and ferruginous manganese ore containing (natural) 17 percent Mn. The Owl Springs Co. shipped ferruginous manganese ore from Manix in San Bernardino County. All production was intermittent, and shipments were small.

Minnesota.—Manganiferous ores from Minnesota are mined on the Cuyuna range and usually average less than 10 percent Mn. However, in 1949, the Hanna Coal & Ore Corp. shipped 3,482 tons averaging (natural) 11.11 percent Mn. In addition, the above company, Pickands-Mather & Co., and Butler Bros. shipped 986,720 tons averaging 5.8 percent Mn.

Manganese and manganiferous ores shipped from mines in the United States in 1949, by States

[1] Containing 35 percent or more manganese (natural).
[2] Value included in total
[3] Containing 10 to 35 percent manganese (natural).
[4] Containing 5 to 10 percent manganese (natural).
[5] Bureau of Mines not at liberty to publish figures.

Montana.—In 1949, Montana supplied 97 percent of all domestic manganese ore, including battery-grade ore. The largest producer, Anaconda Copper Mining Co., produced crude ore from the Butte Hill and Emma mines in Silver Bow County and processed this into nodules containing (dry) 59.1 percent Mn. This company is now successfully producing electric ferromanganese at Anaconda and Black Eagle from its own ores while still supplying eastern furnaces with some of its nodules. In the Philipsburg district, the Taylor-Knapp Co. and the Trout Mining Division of American Machine & Metals, Inc., produced battery-grade concentrates from the Moorlight and Trout groups of mines, respectively. The ore averaged (natural) 66-percent MnO_2. A lower-grade manganese middling averaging (natural) 23.36 percent Mn was also produced in the Philipsburg area.

Nevada.—Four operators produced ferruginous manganese ore averaging (natural) 26.6 percent Mn from mines in Nevada. The Charleston Hill National Mines Co. operating the Black Diablo mine in Pershing County supplied 88 percent of the ore. Blast furnaces at Geneva, Utah, received the shipments.

New Mexico.—Manganiferous ore averaging (natural) slightly below 10 percent Mn was shipped by the Luck Mining & Construction Co. from the Boston Hill mine in Grant County, N. Mex., to furnaces in Pueblo, Colo.

Tennessee.—The Hambright mine in Bradley County, Tenn., shipped a small lot of high-grade concentrates to blast furnaces in the Birmingham area.

Utah.—Ten operators produced ferruginous manganese ores averaging (natural) 20.2 percent Mn from various locations for furnaces at Geneva and Provo, Utah. Shipping points were Delta, Thompson, Stone, Eureka, St. Johns, and Tintic.

Virginia.—The Dominion Manganese Corp. continued to produce small quantities of concentrates from tailings at its mine in Augusta County, Va. In addition, R. M. Green shipped ore containing over 44 percent Mn from Harlow in Campbell County.

CONSUMPTION AND STOCKS

Substantially reduced requirements during 1949 resulted in a 12-percent decrease in the consumption of manganese ore. Domestic mines supplied 10 percent and foreign sources 90 percent, compared with 8 and 92 percent, respectively, in 1948. Three percent was consumed in the manufacture of dry cells, 1 percent went into chemicals, and 96 percent was used in the metals industry. Industry stocks rose from 640,842 tons on December 31, 1948, to 928,349 tons at the end of 1949, an increase of 45 percent. However, these stocks were unevenly distributed, and the demand for ore continued high. The following table shows ores available for consumption in the United States in 1949, without adjustments for changes in consumer or Government stocks.

Indicated consumption of manganiferous raw materials in the United States in 1949

	Ore containing 35 percent or more Mn		Ore and residuum containing 10 to 35 percent Mn		Ore containing 5 to 10 percent Mn	
	Short tons	Mn content (percent)	Short tons	Mn content (percent)	Short tons	Mn content (percent)
Domestic shipments	126,135	56.11	185,066	19.5	1,052,231	5.99
Imports for consumption	1,423,844	46.64	27,266	32.0	[1] 67,466	5.18
Total available for consumption	1,549,979	47.41	212,332	21.1	1,119,697	5.94

[1] Estimated from consumption.

The following table shows the actual tonnages of manganese ore (containing 35 percent or more manganese, natural) and manganese alloys consumed during 1948 and 1949, by type of consumer, together with stocks at the end of the year.

Consumption of manganese ore and manganese alloys in the United States, 1948–49, and stocks Dec 31, 1949, gross weight in short tons

	Consumed		In stock Dec. 31, 1949 [1]	
	1948	1949	At plant, including bonded warehouses	In bonded warehouses only
